Alternators.—Hay.—In a continuation of a serial on the theory of alternators he gives, with the aid of diagrams, the analytical and graphical theory of the "ideal alternator."—Lond. *Elec. Mag.*, April 26.

Single-Phase Commutator Motors.—Sumec.—A conclusion of his serial illustrated by diagrams. He deals with the repulsion motor and the shunt motor.—*Zeit. f. Elek.* (Vienna), May 8.

Lights and Lighting.

Illumination of Incandescent Bodies and Temperature.—Jablonski.—A communication referring to a recent article of Eisler. He points out that his results are in agreement with a former law of Rasch, according to which the total illumination, Φ, increases with the temperature, T, according to the differential equation, $d\Phi/\Phi = Kd\ T/T^2$.—*Elek. Zeit.*, May 5.

Power.

Power Station Design.—Merz and McLellan.—A continuation of their British Institute paper, the first part of which was abstracted in the Digest last week. The authors say that the question of spare plant and its proportion to the output of the station is an important one in design, as also is that of securing the correct relative capacity of the various pieces of apparatus making up a complete unit: the boiler, engine, generator and switch gear. They emphasize that the steam turbine lends itself admirably to dealing with large overloads. They discuss eight different methods in which the station may be rated. In a plant where the load factor over a year may be expected not to exceed 25 or 30 per cent., low cost of production will be facilitated by the engineer considering capital expenditure rather from the point of view of the most economical way of dealing with a peak load. In other words, in estimating the capital cost, he considers that the rating of the station should be based on the maximum possible output which the station is capable of dealing with for one or two hours, making no allowances for spare plant. The authors consider that by proper attention to spares and overload capacity the cost per kilowatt of maximum output of a power station can be reduced from 20 to 40 per cent., depending, of course, on the load factor to be dealt with. They then deal with auxiliary machinery, and recommend electric driving for the machinery in the boiler house and for the circulating and air pumps. For the feed pumps they recommend to install at first steam-driven feed pumps and to use electrically-driven feed pumps for extensions. Concerning the method of electric driving the auxiliary machinery, they recommend to have in view the ultimate adoption of driving from separate generating sets, with the addition of a connection to the main bus-bars to meet emergency conditions. But for the first installment they recommend the use of polyphase auxiliaries operated through stationary transformers from the main bus-bars, without, for the time being, providing any alternative source of supply. They also offer the following possible method as being quite attractive. It consists in driving the whole of the auxiliaries from the particular main unit which they serve by connecting stationary transformers direct to the alternator terminals, these transformers being of sufficient capacity to operate air pumps, centrifugal pumps, stoker, induced-draft fan, and even, if desired, feed pumps—all in permanent connection through a switch with the main unit. In starting up, the switches controlling air pumps and centrifugal pumps may be left in and the field of the main generator excited. These auxiliaries would then start up with the main machine just as if they were mechanically coupled or geared to it. Flexible connections would be provided so that motors, feed pumps or induced draft fans could be used as spares for other sets, but normally each main unit would deal with its own auxiliaries and would be independent of all others. In an editorial discussion of the paper emphasis is laid on the point brought out by the authors that economy in capital expenditure is as important as economy in works cost.—Lond. *Elec.*, May 6.

REFERENCES.

Steam Turbines.—London.—An article illustrated by diagrams on steam turbines for electric generating stations, with some comparisons with the reciprocating engine.—Lond. *Elec.*, April 26.

Emmet.—A paper on new steam turbine developments, illustrated by various diagrams. He deals with the development of the Curtis turbine and gives some notes on the 5,000-kw turbine installed in the new plant of the Chicago Edison Company and of a 2,000-kw machine of the new four-stage type recently tested under the conditions of vacuum and superheat afforded by the Schenectady power station. He thinks that the four-stage machine will hold its own against all competing engines for some time to come, and that it will be extensively used.—*Proc. Engineers' Club, Philadelphia*, April.

Lifting Apparatus.—Reichwald.—An illustrated description of electrical lifting apparatus for iron and steel works, especially of block charging cranes, and loading cranes.—Lond. *Elec. Mag.*, April 26.

Blast Furnace Gas Engines.—Allen.—In a continuation of a serial on the application of electricity to mining and metallurgy he deals with the utilization of the blast furnace gases for driving gas engines.—Lond. *Elec. Mag.*, April 26.

Traction.

Double-Current Generators for French Traction System.—A fully illustrated description of the electric tramway line from Aix to Marseilles. The length of the line is 30 km. and each train consists of a motor car and a trailer and makes the return trip five times per day. Each motor car is equipped with two 36-kw motors. The power plant contains three double-current generators supplying both direct current direct to the line and three-phase currents to step-up transformers, which send high-tension three-phase currents to sub-stations in which the current is changed to direct current by step-down transformers and synchronous converters. The converters are in parallel with the direct-current side of the double-current generators, so that there is a very close interrelation between the different machines in the power plant and the sub-stations. There is a good distribution of the load and the generators supply more or less direct current or three-phase current, according to whether motor cars are nearer or farther away from the power plant. The following advantages are claimed for this system over that of the generation of three-phase currents to converter sub-stations: one sub-station at the power plant itself is avoided; there is no loss at the power plant itself in the conversion of three-phase currents to direct currents; the only high-tension apparatus used are transformers. The main difficulty to be overcome in this system was that the same voltage must exist at the commutators of the double-current generators and of the converters, whatever may be the load. It was, therefore, necessary to compensate for the loss of voltage in the transformers, the line and the converters. Such an automatic compensation was obtained by special construction of the transformers with high self-induction and by compounding the converters. The power house contains three double-current generators, two of 200 kw and one of 100 kw. They furnish direct current at 650 volts and three-phase currents at 400 volts. The voltage of transmission of the three-phase currents is 10,000. There are two sub-stations, one containing one transformer and a 120-kilovoltamp. converter, while the other one contains two sets of the same kind.—*L'Ind. Elec.,* April 25.

Direct-Current Versus Single-Phase Traction.—HOBART.—The conclusion of his article. The author continues to discuss Lincoln's comparison of the single-phase and direct-current system for a 60-mile road. He introduces such corrections for Lincoln's single-phase figures as he considers to be justifiable, and he substitutes, moreover, for the 600-volt, direct-current system with sub-stations a system with two direct-current generating stations, located respectively 15 miles from each end of the system and 30 miles from one another. These stations he assumes to be equipped with slow-speed 1,350-volt direct-current generators, and the cars are fed at an average voltage of 1,300. Each car carries two 650-volt motors connected in series and operated as a 1,300-volt unit. The acceleration is rheostatic. He gives a table of comparative costs and arrives at the result that the single-phase system is 12 per cent. higher in first cost and 7 per cent. higher in operating expenses than the direct-current system for the items which he takes into consideration. He assumes two power houses for the direct-current system, since this arrangement is fairly suitable for Lincoln's line and for 1,350 volts at the generators; but for extensive lines polyphase generation from a single station would often be preferable. He concludes that his comparison affords ground for the opinion that the superiority of the single-phase motor for other than main line work is as yet by no means a foregone conclusion. Nevertheless, the single-phase commutator motor represents a very important advance. It is beyond all comparison superior to the single-phase motor without commutator, and is already not greatly inferior to polyphase motors and direct-current motors. This is an excellent record for such a brief period of development.—Lond. *Elec. Rev.,* May 6.

Electric Headlight.—CARNEY.—An abstract of a paper on the electric headlight as an adjunct to modern railway practice. It acts as a safety device by giving a warning to the public that a high-speed train is approaching. But an electric headlight burning in a switch-yard is a nuisance. One main disease of it is the effect of the diverging rays on the vision of the engineman during snow, rain or mist. To overcome this difficulty a cylindrical extension about 15 in. long has been fitted to the ordinary headlight. This gives a sharper pencil of light and seems to illuminate the track better than the standard one.—*Eng. News,* May 19.

Traction Motor for Small Gauge Roads.—BOEHM AND RAFFAY.—An illustrated review of the development of traction motors by the Oerlikon Company with special reference to a 900-volt, 110-hp motor for small gauge roads. It weighs 1,700 kg., when tested for one hour with a load of 105 hp, the increase of temperature in the field coils was 70° C. over the temperature of the surroundings, while the commutator and the armature had a smaller temperature. The insulation of the windings was tested with 3,000 volts alternating currents. —*Elek. Neu. Anz.,* April 15.

Egypt.—A description of the first Egyptian steam line to be converted to electric traction. The combined system comprises the Alexandria Traction Company and the Alexandria & Ramleh Railway. The main line of the latter is a standard-gauge, double-track road joining Alexandria and Ramleh. The principal features are the use of heavy rails, center-pole construction, high-voltage alternating-current transmission system with rotary converter sub-stations and compound condensing engines in the power plant.—*St. R'y Jour.,* May 7.

Electric Traction in Germany.—JACQUIN.—A description with maps of the tramway systems of Hamburg and Kiel.—*La Revue Elec.,* April 30.

Rail Bonding.—SHEARDOWN.—The first part of a paper read before the Dublin Section of the British Institute of Electrical Engineers, on tramrails and rail bonding. The author states that while there have been many forms of solid or continuous rail joints thought out and patented, yet the only three which have had any amount of use in practice are the Falk cast-welded joint, the electric-welded rail joint of the Lorain Steel Company, and the thermit joint. In the present installment the first two mentioned systems are described.—Lond. *Elec.,* May 6.

INSTALLATIONS, SYSTEMS AND APPLIANCES.

An Apparatus for Making out Bills to Electricity Consumers.—BIERMANN.—A paper read before the Berlin Electrical Society. The author emphasizes the amount of money which is yearly spent by large electric supply companies for rendering the bills to their customers. The meter is read by a man, then at the office the consumption is calculated, multiplied with the constant of the meter, again multiplied with the rate at which the energy is charged for, the bills are made out and the money is collected. Then there is much trouble with customers, who claim that their meter is wrong. He describes a meter in which most of the above work is done in the meter itself and the consumer is always enabled to read at once from the meter how much money he has spent for electric light every day. If there is really something wrong about the meter the consumer will soon find it out and then put in his claim at once, and there will not be any trouble at the end of a longer period. His meter is essentially a combination of an ordinary electricity meter with a calculating apparatus and a printing device. In this way the bill is directly made out by the meter. The instrument is described in detail and illustrated.—*Elek. Zeit.,* May 5.

WIRES, WIRING AND CONDUITS.

Earthing of the Neutral Point in Three-Phase Systems and the Watt Loss in the Dielectrics of Cables.—HUMANN.—An article in which the author calls attention to the advantages in earthing the neutral point in three-phase systems. The safety of the system against accidents is thereby increased. At the same time the watt loss due to dielectric hysteresis in the cable network is considerably diminished. This loss is for high-voltage networks considerably greater than is generally assumed, and this loss exists whether current is consumed in the network or not. The author has made experiments with a three-core, three-phase, high-tension cable of 3×25 sq. mm. copper cross-section, of 890 meters length. The insulating layer of impregnated paper was 6.8 mm. thick between copper and lead, as well as between the different copper conductors. His results are applied to a comparison of the watt loss in the following two cases: In the first case the neutral point is earthed; in the second case one phase is earthed. He remarks that the latter case may easily occur in practice. For 100 km. of his cable, operated at 5,000 volts, the loss amounts to about 23,000 kw-hours per year, if the neutral point is earthed, and to about 35,200 kw-hours, if one phase is earthed. If the cost of 1 kw-hour is assumed to be 2.5 cents, the earthing of the neutral represents a saving of $304.40. For higher tensions this saving is much more considerable; for 10,000 volts it amounts to $1,209. The earthing of the neutral point is preferably carried out in the power house by means of a special conductor of sufficient cross-section.—*Elek. Zeit.,* May 5.

Inductive Voltage Drop in Parallel Three-Phase Lines.—LICHTENSTEIN.—The conclusion of his article. In practice the voltage drop of parallel conductors carrying three-phase currents is often calculated as follows. To determine the voltage drop in the set of conductors 1 and 2 one calculates the voltage drop in conductor 1 and the voltage drop in conductor 2 and forms their geometrical sum. By voltage drop in conductor 1 is meant the geometrical sum of the ohmic voltage drop and the inductive voltage drop per conductor, the latter being calculated by the formula for two parallel single-phase conductors. This method of calculation, if applied to three conductors in one plane (as is often the case in three-phase railways) gives accurate results only for the voltage drop between the two outers of the three wires. For the voltage drop between 1 and 2 and for the voltage drop between 2 and 3 the results are wrong by a few per cent. The author emphasizes, however, that by such a method of calculation the term "voltage drop in a conductor" is introduced, which he endeavors to show has no physical significance. The calculation of the voltage drop is much easier if the three conductors are so arranged that a cross-section through them gives an equilateral triangle.—*Zeit. f. Elek.* (Vienna), May 1.

ELECTRO-PHYSICS AND MAGNETISM.

Revolving Electrostatic Field.—GUYE AND DENSO.—An illustrated description of an arrangement for producing a revolving high-tension electrostatic field, which they use for making experiments on the dielectric hysteresis in revolving fields. The arrangement is shown in Fig. 7, in which A_1 and A_2 are two points connected to a single-phasealternator. R is a non-inductive resistance, C an adjustable capacity and L an induction coil. A_1, B and A_2 are connected to the four plates, 1, 2, 3, 4, as shown. The authors derive the mathe-

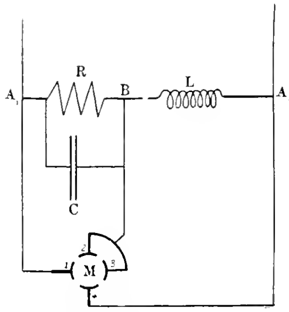

FIG. 7.—REVOLVING ELECTROSTATIC FIELD.

matical relations which must be fulfilled between R, C and L, in order to produce a circular revolving electrostatic field at M.—*L'Eclairage Elec.*, May 7.

Conductivity of Sodium.—BERNINI.—An account of an experimental investigation of the influence of temperature on the electric conductivity of sodium. The main results are that sodium is one of the best conductors of electricity; its conductivity decreases with increasing temperature, and it appears that the law of proportionality is nearly fulfilled within the limits of his investigation; the temperature coefficient is larger for liquid sodium than for solid sodium; the change of resistivity at the melting point is represented by a sudden rise, in the proportion of 1 to 1.337. The specific resistance at 0° C. is 0.050407 and at 120° C. 0.093062. Just below the melting point, at 97.3°, it is 0.0655, and just above the melting point, at 98.5°, it is 0.088. The melting point is, according to his measurements, 97.633° C.—*Phys. Zeit.*, May 1.

REFERENCES.

Hertzian Waves and Phosphorescence.—GUTTON.—An account of experiments in which he found that not only does the induced e.m.f. due to the variation of a magnetic field brighten a calcium sulphide screen, but Hertzian oscillations, producing, as they do, very intense e.m.f's, do the same.—*Comptes Rendus*, April 18; Lond. *Elec.*, May 6.

Flames Between Electrodes.—An account of an experimental investigation of the electric current through flames placed between two nearby electrodes, some experiments being made with calcium oxide electrodes.—*Phys. Zeit.*, May 1

UNITS, MEASUREMENTS AND INSTRUMENTS.

System of Electrical Units.—FOURNIER D'ALBE.—A communication referring to the suggestion of Robertson, whose radical changes could only be justified on the ground of finality, but such a claim cannot be made for them. The advance of the electron theory is gradually reducing the whole of electromagnetic theory to a theory of the electron at rest and in motion. The present author emphasizes that the natural unit of electricity is the electron itself, or, since it is inconveniently small, some multiple of it, preferably a trillion electrons, which might be called the "trelectron." A coulomb would be about five trelectrons. A current of one ampere would be generated by the passage of five trelectrons per second through any cross-section of the conductor. One trelectron would repel another at a distance of one meter in air with a force of 40,000,000 kg. Putting ξ for the new fundamental unit of electric quantity he gives the new dimensions of several electric units; for instance, current $= \xi T^{-1}$. The conductivity comes out as the density of electrons multiplied by mobility, the mobility being the steady velocity acquired by an electron under unit force acting upon it within the conductor.—Lond. *Elec.*, May 6.

Hay.—Another communication on the same subject. He emphasizes the innate conservatism of human nature. "Will any number of resolutions or recommendations passed at international electrical congresses induce the host of designers to abandon their present methods merely in order to satisfy the fastidious taste of their scientific confrères? And if not, what advantage is there in tampering with the existing system, beyond the somewhat imaginary one of eliminating the innocent yet much-abused 4π from certain equations, merely in order to have it reappear in others?" He thinks that "such unfamiliar terms" as abfarads, abcoulombs, gausses, gilberts, abstatvolts are "certainly more remarkable on the score of originality than on that of euphony." He thinks there is the danger with any attempt to alter the existing system that it would create two distinct systems, one for use by theorists and the more enlightened engineers, the other by those who are merely concerned with the more or less mechanical application of general principles to practical problems. The only result would be to make the language of the scientific investigator much less intelligible to the practical man than it is at present.—Lond. *Elec.*, May 6.

Measuring the Energy of Short and Rapidly Decreasing Electric Currents.—WEICHSEL.—A mathematical article on the measurement of the energy of very short and very rapidly decreasing electric currents; thus problem is of importance for telegraphy and electric clocks. He shows that if a dynamometer is used with a period of oscillation which is very large compared with the duration of the current to be measured, the reading of the first deviation of the needle gives the time integral of the squares of the instantaneous currents. On the other hand, a ballistic galvanometer gives the time integral of the instantaneous currents. If the current, the energy of which is to be measured, is sent through the fixed coil, while the movable coil, in series with a very high non-inductive résistance, is shunted across the terminals of the apparatus in which the current is consumed, the energy of the short and rapidly decreasing current is proportional to the first deviation of the needle of the instrument. He gives rules of the application of Thomson's quadrant electrometer and of the Curie electrometer. His equations are valid for undamped instruments only. He finally introduces the corrections which must be made on account of the damping.—*Zeit. f. Elek.* (Vienna), May 8.

REFERENCES.

Pyrometry.—GHEURY.—The first part of a paper on the various methods used in pyrometry. He dwells specially on the three standard methods which have actually left the experimental stage and are of current use in practice, that is the gas thermometer, the resistance thermometer and the thermo-electric thermometer.—Lond. *Eng'ing*, May 6.

Barbed Damping Device.—FAVÉ AND CARPENTIER.—A description of a new device for damping oscillations which combines a very small moment of inertia with a high damping coefficient. It consists of a stellar arrangement of very thin glass fibres or natural hairs, fastened to the oscillating needle with its plain horizontal and its center in the axle of oscillation. The fibres used have a diameter of about 1/10 mm.—*Comptes Rendus*, April 18; Lond. *Elec.*, May 6.

MISCELLANEOUS.

Comet Tails.—An editorial summary of the hypotheses which have been proposed for the explanation of comet tails. Fitz Gerald has suggested that the Maxwellian light pressure exerted by solar radiation on the molecules of a gaseous cometary envelope might be the cause of the observed curvatures of the appendages. A difficulty, however, arises from the small absorption of radiation by gases, and Arrhenius has suggested that condensed particles of matter should replace the molecules of Fitz Gerald's hypothesis. On the basis of this hypothesis Schwarzchild has calculated the repulsion exercised by the sun's total radiation on a single particle and compared that force with the sun's gravitational attraction. He estimated that, on particles of the most favorable size, the radiation pressure might reach a magnitude about 20 times the gravitational attraction. As a matter of fact, astronomical measurements indicate a solar repulsive force about 40 times the attraction of gravitation. Thus, with the most favorable postulates, the Maxwellian light pressure theory has not yet afforded a complete explanation of the main phenomena. Perhaps it is a complex effect, however, some other distinct self-contained theories have been suggested. Fessenden thinks the tail may consist of particles carrying negative electricity which move under solar gravitation, nuclear electrostatic attraction and the electric repulsion of a negatively-charged sun. J. J. Thomson has suggested that the sun's ultra-violet radiation disengages from the nucleus negative ions which are repelled by radiation pressure. This supposition seems to require the existence in solar radiation of Hertzian waves. Lastly, Bois has suggested that radioactive substances in the nucleus may give rise to charged atmospheres, which move in the electrostatic field of the sun.—Lond. *Elec.*, May 6.

Radium Rays for the Blind.—London.—An account of experiments in which he attempted to utilize radium rays for the instruction of the blind. Although the rays probably exert some feeble effect upon the optic nerve, they act in a much more pronounced manner upon the retina, and whatever effect can at present be produced is conditional upon the retina, or some small portion of it, having retained its susceptibility for light. If a box containing a radium preparation is approached towards the head of a person whose eyes are bandaged, he perceives a general diffused luminosity which is centered to some extent towards the direction of the box. With some practice the subject can indicate the direction in which the box is situated, and if the operator traces lines and curves in front of his eyes, with the box, he can trace them out after him with a fair amount of accuracy. But the practical value of these observations is annulled by the fact that the rays are very dangerous to the eyes, leading easily to retinitis and blindness. On the other hand, the rays may be usefully employed in conjunction with a platino-cyanide screen. The author encloses such a screen in an opaque frame, which is held in front of the eye in a dark room. Objects are shown as silhouettes on the screen, and the blind subjects are told their shapes as first, with the aid of the sense of touch, and when they acquire some practice they are able to trace them out themselves. In this way the reading of raised letters is greatly facilitated, the vague visual impression strengthening the actual perception. Ordinary screens illuminated with electric light were also tried, but were found to irritate the eye by the heat rays.—*Archives d'Elec. Medicale*, April 25; Lond. *Elec.*, May 6.

REFERENCES.

Electric Separation of Oil from Condensed Feed Water.—A note on experiments made by Davis and Perrett, of London, who found that whereas with untreated condensed water it was practically impossible to remove the oil by mechanical filtration, this can be done if the water is first subjected to electrolytic action. For this purpose some tap water must be added to the mixture in order to increase its conductivity. The water is passed through a wooden tank between iron electrodes, a potential of 50 volts being maintained between adjacent plates, and is subsequently filtred.—*Power*, April.

Electricity in Agriculture.—Guarini.—The first part of a serial on electricity in agriculture. The author emphasizes that experiments and observations have shown that electricity is able to have good effects on the growth of plants. This influence may be either direct by the electrification of the ground, the plant, the atmosphere, or indirect, by means of lighting with the voltaic arc. He begins to give a summary of the results obtained in this direction by various investigators.—*L'Elec.*, May 7.

Radio-Therapeutics.—Bergonié.—An account of a case of cure of a cancroid cancer of the eyelid by Röntgen rays. The patient was a woman of 63 years, suffering from cancer of the eyelid and the orbid of 20 years' standing, but recently accelerated. Röntgen rays of sufficient intensity to penetrate the thorax were applied to the eye through an aperture in a lead screen during 11 sittings of five minutes each, extending over a month. Six weeks after the treatment the cancer had completely disappeard, laving the eye closed, indeed, but covered with a normal skin through which the eyeball could be felt to be in a normal condition.—*Archives d'Elec. Medicale*, April 25; Lond. *Elec.*, May 6.

New Books.

La Telegraphie Sans Fils. By André Broca. 2 ième Édition. Paris: Gauthier-Villars. 234 pages, 52 ills. Price, 4 francs.

André Broca, who is professor of physics in the faculty of medicine in the École Polytechnique, Paris, issued the first edition of "The Telegraph Without Wires" in 1890, and his object at that time in writing the treatise was to present a non-technical account of the electromagnetic theory of light and its relation to wireless telegraphy in as simple a manner as possible.

Since then, as Prof. Broca states, in the preface of the second edition, the art has been very greatly extended and the theory of high frequency currents as well as the relation of electrical resonance to syntonization has become a constituent part of wireless telegraphy, and these subjects have been treated in the latter book. There are twelve chapters in all, the synthetic arrangement following more or less closely the works of other foreign writers on the same subject. There is little or nothing new in Broca's book, but the matter included is, however, presented in a readable manner.

Die Anwendung der Elektrizitat für Militarische Zwecke. By Dr. Friedrich Wachter. Leipzig: A. Hartleben. 212 pages, 66 illustrations. Price, 4 marks.

The author has prepared a small handbook of practical information for those interested in the practical applications of the subject. The book is devoid of algebra or quantitative laws, and is divided into five chapters. The first is introductory and preliminary. The second is on military telegraph apparatus, including wire and wireless telegraphy, telephony and optical telegraphy. The treatment is very brief.

The third chapter relates to mine firing. The fourth refers to electric chronographs for determining the velocity of projectiles. This is probably the best chapter and the most modern. The last chapter is devoted to electric lighting motive power and miscellaneous applications.

In many directions the cuts and descriptions refer to archaic forms of apparatus and the book is not up to date in these respects. The treatment is, however, clear, concise and practical.

Theorie und Anwendung des Elektrischen Bogenlichtes. By H. Birrenbach. Hannover: Gebruder Janecke. 350 pages, 266 illustrations. Price, 9 marks.

This volume is a text-book of arc lamps, written by an engineer for engineering students. The graphical method of representing relative magnitudes is developed throughout and brief algebraic formulæ are used where necessary.

The book is divided into seven chapters. The first chapter contains a brief history of the subject and the general laws connecting current, pressure and arc dimensions. The second chapter gives a comparison between various sources of light, including enclosed and open arc lights, in reference to power, cost, etc. The comparison appears in general as unfavorable to enclosed arc lamps—the condition reverse to that holding in this country. Chapter III deals with arc photometry and the units employed. Chapter IV relates to the construction of arc lamps. The mechanisms of the more common forms of German arc lamps is described at considerable length. Chapter V considers the various methods of connecting arc lamps. Chapter VI is devoted to accessory arc lamp apparatus, such as transformers, resistances, indicators, etc.

Chapter VII relates to the applications of arc lamps. These are classified as follows: A, general applications; B, street lighting; C, interior lighting; D, projectors; E, photographic applications; F, medical applications.

The book concludes with a complete list of German arc light patents and an index of contents. The text is clear and the illustrations are excellent. The book will be valued by those interested in the practice of German arc lighting.

New Electric Organ for Denver.

One of the latest examples of church organ manufacture is now being installed in Denver, Colo., at the First Church of Christ, Scientist, Logan and Fourteenth Avenues. The instrument is of the electro-pneumatic type, and when it is completed will cost about $22,000. It contains about 3,200 separate pipes for tone production, ranging from what is called a "speaking length" of 32 ft. to a length of 3/8 of an inch, giving a range of audible vibration of from about 30 per second to 35,000 from the extreme bass to the extreme treble tones—that is, from the "tibia profundissima" to the "harmonic piccolo." The organ is composed of six separate organs: pedal, solo, swell, great, orchestral and echo. The keys are in four banks, each bank containing five octaves and one note, making a total of 244 keys. Each key sounds its proper note by closing a 5-volt circuit through a small horseshoe magnet about 2 in. long, wound with No. 22 wire. The armature of each magnet is about the size of a five-cent piece and covers small air holes which admit the proper air pressure to the organ pipes. This pressure varies from that which will support a water column 5 in. high to that required to support 15-in. column. The electric contacts which are made by the keys are composed of gold wires and platinum strips. These contacts have an extremely low resistance, and do not oxidize as they are used. Current for the operation of the electro-magnets, which open and close the air valves admitting air to the pipes is supplied by a battery of Edison-Lalande cells, consisting of three parallel groups of five cells in series in each group. One group of five cells will operate the magnets.

The total number of stops in the organ is 48. The stops are operated by keys instead of the usual plugs, the organ being one of the only three in America to have this attachment. It is the second organ in the country to have double touch pistons, there being 28 of these peculiar button contacts on the four banks of keys. The object of these pistons is to enable the organist to bring various sets of stops into service without taking his hands from the key banks. Each piston makes two successive contacts, and each contact throws certain stops into operation, so that the old annoyance of having to pull out a long series of stops in securing various tone combinations is largely done away with, constituting an interesting example of the adaptation of the electric circuit as a time-saver in the complex process of rendering a difficult musical score. The platinum and gold contacts alone are valued at over $400. Some of the pedals have double contacts also; an innovation in organ design.

The echo organ is placed in the roof of the auditorium with a set of chimes. The main organ is placed behind and above the reading platform, and all the pipes and mechanism are concealed behind a wooden lattice of handsome design. The console, or playing desk containing the keys, pedals, stops and contacts, is stationary on the auditorium floor at the right of the platform. Compressed air brought through small lead pipes to the console is the agency for producing tonal effects set in combination by the various stop keys.

The organ receives its air supply from a No. 7 Sturtevant blower belt-driven from a 7½-hp, 500-volt, direct-current, two-pole General Electric shunt motor running at 1,650 r.p.m. This apparatus is located in the basement of the church, and is connected with the organist's switch cabinet by cables running in iron-armored conduit. The motor is run open, its closed capacity being but 5.5 hp. The organist's cabinet is a fire-proof recess lined with galvanized iron and asbestos located beneath the reading platform at the left of the console seat. It contains a double-pole, single-throw knife switch and a rheostat with automatic release, both of General Electric make. The organist thus can easily start the blower motor by simply turning to the left and without leaving his seat. The air supply from the blower is further controlled by a damper valve in the flue which leads from the blower room to the organ loft. Over 22 miles of electric cable are installed in the organ proper, and the various parts are lighted by 108-volt, 16-cp incandescent lamps, to facilitate inspection and repairs. This organ is the first in America to be equipped with "tibia plena" pipes.

The church building is a handsome new structure of lava stone, quarried near Salida, Colo. It is admirably lighted throughout by widely distributed incandescent lamps of the frosted bulb variety. The seating capacity of the building is about 1,000 and the total cost, approximately, $150,000. The organ is the work of the Austin Organ Company, of Hartford, Conn., to whose representative, Mr. Herbert Brown, the writer is indebted for these details.

Exhibits in the Electricity Building, St. Louis.

In the southwest corner of the Electricity Building is a complete exhibition of electric heating appliances made by the American Electrical Heater Company, of Detroit, Mich. The modern housekeeper finds that electricity is first a luxury then a necessity when the many labor-saving electrical appliances are placed at her disposal. With the electric smoothing iron she can laundry her own shirtwaists and neckwear, doilies and lingerie, and save many misgivings about her hand-made lace and embroidery. She simply removes a lamp from a socket, inserts a plug attached to a flexible cord and the iron keeps at a constant heat. The company shows a full line of cooking utensils, including complete ranges with ovens, boilers, etc. Individual appliances such as chafing dishes, coffee and tea pots, egg boilers, hot water urns, curling iron heaters are shown in different styles and sizes. Nearly every manufacturing industry needs some tool or apparatus to be heated, and electricity gives the most perfect heat known, as the heat can be conducted to a certain part of the appliance and kept there continuously at constant temperature, allowing the operator to do more and better work than by any other method. Over sixty different styles of pressing and smoothing, or laundry irons, are shown, ranging in weight from twenty ounces to thirty pounds. House and office heaters are shown as well as ovens, plate warmers, foot warmers, glue pots, griddles, pancake cookers, toasters, small stoves like a stove lid from four inches to

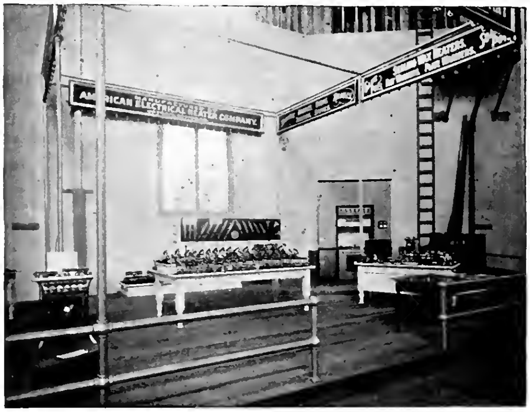

FIG. 1.—EXHIBIT OF AMERICAN ELECTRICAL HEATERS.

sixteen inches in diameter, laboratory plates giving seven heats in different sizes, branding irons for branding cigars and corks, wood-bending forms, soldering irons from ten ounces to four pounds in weight, and numerous other articles. Mr. B. H. Scranton, the president and general manager, was on the grounds for three weeks getting the exhibition in shape, and it was completed when the gates opened on April 30.

The space occupied by the Acheson Graphite Company, near the main entrance of the building, contains miniature electric furnaces which illustrate the processes of Mr. E. G. Acheson of manufactur-

FIG. 2.—ACHESON GRAPHITE EXHIBIT.

ing graphite from anthracite coal or similar raw materials. The different grades of graphite and electrodes of various sizes and forms will be shown, the latter containing practical working samples of different anodes and electrodes as used by the customers of this company for electrolytic work. They illustrate the different methods of machining and assembling the graphite into economical anode forms. For electric furnace work, the electrodes can be joined together end to end and fed into the furnace one after the other as consumed without interruption of the furnace. The graphite bulk products will illustrate the importance of this article in the manufacture of paint, dry batteries, stove polish, motor-generator brushes, etc. Special attention is given to the use of this form of pigment for high-grade protective coatings on structural iron and steel.

The Hutchison Acoustic Company's booth and exhibit were completed at the opening and Mr. M. R. Hutchison gave demonstrations of his acousticon and massacon, electromagnetic instruments for the alleviation of deafness. Two congenital deaf mutes were

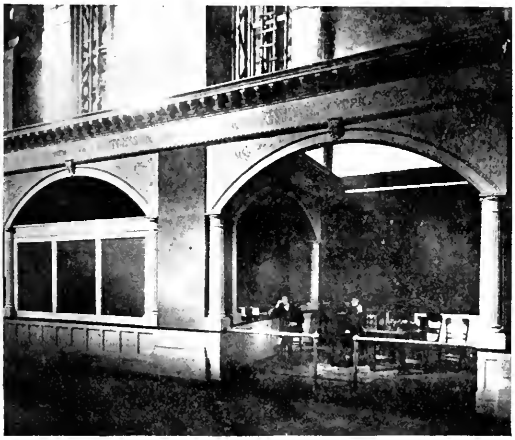

FIG. 3.—EXHIBIT OF HUTCHISON ACOUSTIC COMPANY.

provided by the Educational Department and these boys, who had heard no sound from birth, were made to hear music and the voice by using the acousticon. This instrument consists of a small battery, a specially-designed telephone receiver, and a transmitter which amplifies the sound and imparts the waves to auditory nerves. The massacon is a magnetic instrument which emits sound waves in sharp saw-tooth form and sets the ear drum and auricles in vibration, which stimulates them the same as massage to weakened muscles and restores the ear to normal condition.

The only underground exhibit in the Electricity Building is that of the McRoy Clay Works and the Standard Underground Cable Company near the northwest corner entrance. The installation of the conduit, manholes and cables is just as they are placed beneath the street surface. An excavation is made at one side so that the cross-section of the whole subsurface installation is open to view, as shown in the illustration. The cable reel and capstan are placed at the manholes ready for actual operation. Over the conduit aerial lines and cables are extended between two poles, and these serve to indicate the method of connection and distribution between the

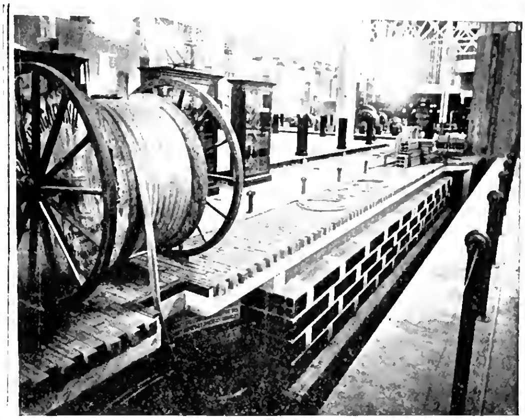

FIG. 4.—EXHIBIT OF M'ROY CLAY WORKS AND STANDARD UNDERGROUND CABLE COMPANY.

overhead and subsurface lines. A number of cabinets contain samples of telephone, lighting and power cables made by the Standard Underground Cable Company.

The Edison historical exhibit, made under the auspices of the Association of Edison Illuminating Companies, contains a collection of early generators, motors and other apparatus constructed under the personal direction of Mr. Edison when electrical engineering was in its infancy. About the walls of the exhibit spaces are hung photographs of the pioneers and their early work. The Jumbo dynamo, made by the Edison Machine Works, direct-connected to a high-speed engine, forms an interesting comparison with the model of the General Electric 10,000-hp Niagara generator, which

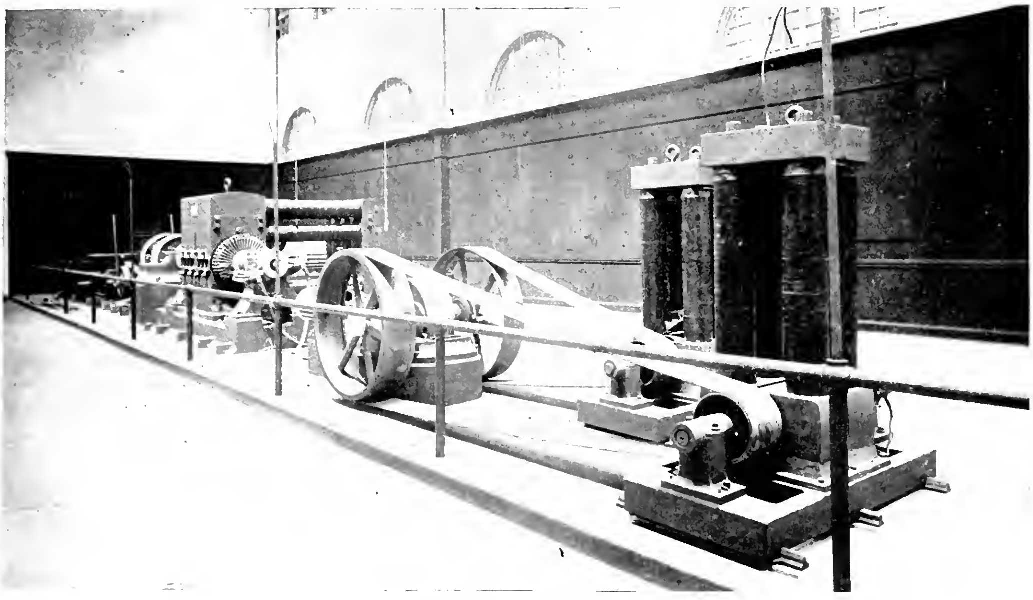

FIG. 5.—EDISON HISTORICAL EXHIBIT.

is across the aisle. The first Edison electric locomotive with its passenger car shows in a graphic way the progress in transportation made since 1880.

The photograph of the British section reveals the splendid display of electrical and scientific instruments made by the English manufacturers. Most of these instruments have been tested and have certificates from Lord Kelvin's laboratory or the National Physical Laboratory. The General Post Office makes an excellent display of the telegraphic apparatus used in Great Britain. Kelvin and

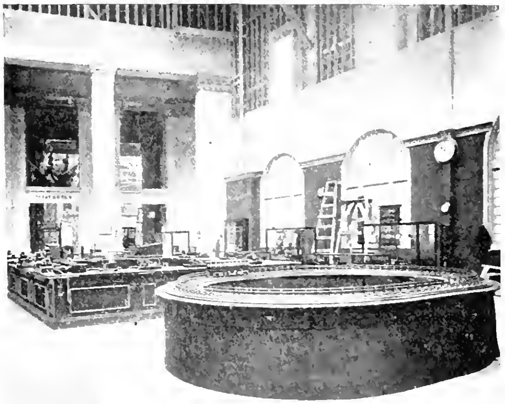

FIG. 6.—ENGLISH EXHIBIT.

James White, of Glasgow, and Muirhead & Co., of Kent, have cases of galvanometers, condensers, standard cells, ammeters, voltmeters and other instruments of precision. In the foreground may be seen a working model of Behr's monorail and high-speed car as authorized by act of Parliament for the railway between Manchester and Liverpool, to be operated at a speed of 110 miles per hour.

The greater part of the space of the Wagner Electric Company, of St. Louis, in Section 6, is occupied by the various applications of single-phase alternating-current motors. This includes the standard form, enclosed, semi-enclosed and back-geared types, from 1/4 to 35 hp. The notable feature of these motors is their starting under

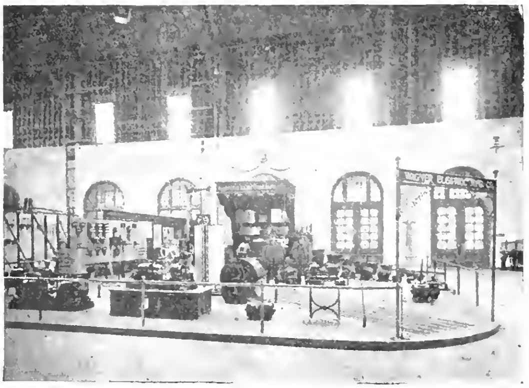

FIG. 7.—EXHIBIT OF WAGNER ELECTRIC MANUFACTURING COMPANY.

load by simply closing a switch. Such a simple starting arrangement makes the motors specially applicable to pumps for different kinds of service, carbonators, as used in drug and confectionery stores, and fans. The noiseless operation of the motors has won them a place for organ-glowing as applied to ordinary bellows in connection with a speed-varying pulley and special centrifugal pressure blower. Other industrial applications are shown in operation, such as machine tools, bakery machinery, etc. In this connection a special speed-changing device is exhibited whereby a machine tool with a single-phase alternating-current motor has all the advantages of control that it would have with a direct-current multivoltage drive. A standard line of transformers from 6/10 kw to 50 kw are shown, in different types of self-cooled, water-cooled and air-blast. A handsome five-panel switchboard is erected at one side, and carries a full equipment of instruments and oil-break switches made by the Wagner Company. Two of the panels are for the operation of the motors and the other apparatus in the exhibit. In the Wagner booth are many interesting photographs and diagrams showing the performance of the various types of machines. There is an office equipment and telephone connection with the down-town office, which are freely and courteously at the disposal of visitors.

The exhibits of electro-therapeutic apparatus are centers of interest to the visitors on account of the high-potential discharges and the X-ray demonstrations. One of the most attractive of these is that of W. Scheidel & Co., which is near the main entrance in Section 4. There is exhibited a complete line of standard X-ray coils, mercury turbine interrupters, Oudin resonators, rheostats, operating and coil tables complete with volt and ammeters, motor and primary rheostats, switches and split-second-stop watches, cab-

FIG. 8.—EXHIBIT OF W. SCHIEDEL & CO.

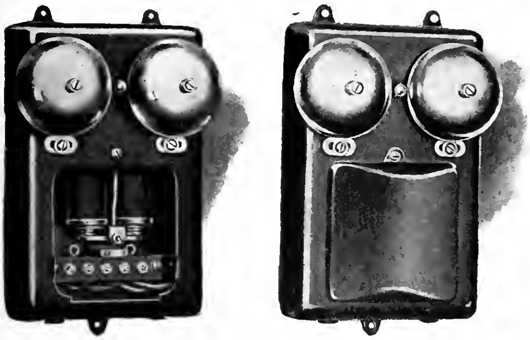
inets containing complete outfits, illuminating cabinets, various tubes, rectifying interrupters for transforming alternating current into direct-curent, fluoroscopes, storage batteries, tube stands, shields and electrodes for local and therapeutics treatments, and a large collection of photographs. Physicians and laymen alike are attracted by the high-potential, high-frequency currents produced by the Oudin resonator, which operates in conjunction with a Leyden jar. The alternating discharge of the jar may be at the rate of a million a second, but by placing a large resistance in the circuit the oscillations are dampened. In order to get from the oscillations of the Leyden jar circuit, currents of high frequency, three different types of machinery are used, namely, the hyperstatic, in which the therapeutic currents are of high potential and are produced by induction; the d'Arsonval spiral or coil, in which currents of low potential are shunted from the Leyden jar circuit by self-induction, and the Oudin resonator.

The resonator consists of a large helix of heavy copper wire, on the lower part of which are passed strong oscillating currents from Leyden jars, which are excited by a coil of sufficient capacity. The upper and longer portion of the helix is not traversed directly by these currents, but is thrown into electric vibration, in harmony with the oscillating currents in the lower part; and these vibrations have a much greater range than the original oscillations. The resonator is regulated by shifting the movable contact near the base of the coil, in front; by varying the rate of interruption of the primary current, and by varying the spark-gap of the resonator. This apparatus can be used as a substitute for static machines, and for Finsen light in the treatment of many forms of disease. All the Scheidel apparatus is connected for operation and a competent demonstrator is in attendance at all times.

Common Battery Telephones.

The Kellogg Switchboard & Supply Company, of Chicago, is constantly adding to and improving its telephonic apparatus, and we now illustrate its latest types of desk telephone and desk set box. In the desk telephone the tubular construction does away entirely with the unsightly wear or tarnish caused by handling the usual nickel-plated standard. The mechanism is dust-proof and cannot be tampered with as it is entirely enclosed.

A tubular standard and a hollow brass base support and contain all the parts of the stand. The transmitter is adjustably hinged to the top of the standard, and two cords, concealed their entire length, lead from it to their proper connections in the base. This base is



FIGS. 1 AND 2.—DESK SET BOX, OPEN AND CLOSED.

covered by a handsome nickel-plated brass shell, and in it are mounted a condenser, the hook switch, a retardation coil and two rubber terminal blocks for the receiver and desk stand cords. The condenser is of a special construction designed to give a comparatively large capacity in a small space. The retardation coil is also of an especially

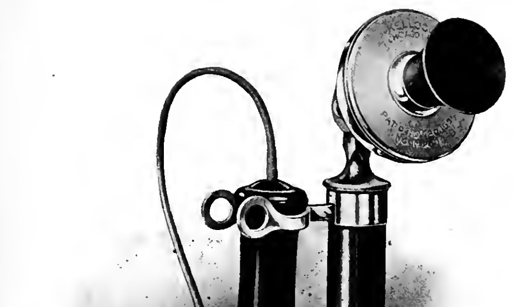


FIG. 3.—DESK TELEPHONE.

compact design. All parts in the base are normally enclosed by an iron plate which fits over the bottom.

The lever of the hook switch is a long L-shaped piece pivoted on the standard, the short arm of which terminates in the fork for the receiver while the long arm extends down through the hollow standard to the base, where its insulated end engages with the hook spring switches. This lever is actuated by a stiff leaf spring.

The new type of Kellogg desk set box is also illustrated herewith open and closed. The compact box is shallow so that it may be mounted in any convenient place about a desk without being in the

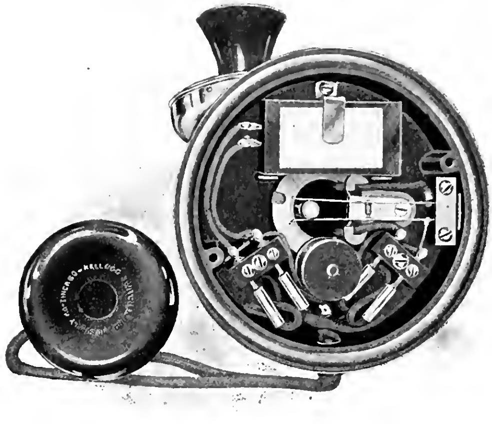

FIG. 4.—VIEW OF INTERIOR OF DESK SET BASE.

way. Standard parts are mounted in a pressed steel case, finished with black enamel. There are enclosing lids front and back, which when removed expose the ringer, condenser and connecting rack. It is intended for either individual or two-party line service and besides being in black is furnished also in white or maroon enamel.

Power and Mining Machinery Contracts.

The Power & Mining Machinery Company (formerly the Loomis-Pettibone Gas Machinery Company, of New York, and successor to the Holthoff Machinery Company, of Cudahy, Wis.), New York, has just been awarded a contract for the equipment of the new power plant of the Wellington Meat Export Company, a British capitalized concern, which operates a large works at Wellington, New Zealand. The value of the contract is almost $125,000. The existing power plant is operated by steam, and owing to the excessive cost of coal in that part of the world the installing of the gas generating equipment and electrical machinery, for which the Power & Mining Machinery Company has the complete contract, is expected to result in a saving of 75 per cent. in fuel.

There will be a 3,000-hp gas generating outfit comprising six generators of 500-hp capacity each, to operate on the Loomis-Pettibone system. Crossley two-cylinder horizontal gas engines will be installed. There will be nine engines aggregating in all 1,415 hp. Three will be of 225-hp capacity each, direct-connected to 150-kw, direct-current, 250-volt electric generators. There will also be two 200-hp Crossley engines, one 160-hp and also a 100-hp engine, which are to be used for driving refrigerating machinery. Gas generated by the same plant will also be used for the large melting and heating kettles. The entire power plant will be in full operation, it is anticipated, in December of this year. Mr. W. H. Morse, one of the Power Company's engineering experts, is now in New Zealand regarding the contract. The electric generators have not yet been purchased.

The Power & Mining Machinery Company will next week complete the installation of the largest power plant of its description in the hemisphere, at Velardena, in the vicinity of Durango, Mexico. The contract was secured from the Velardena Mining & Smelting Company, which concern is controlled by the Guggenheim Exploration Company, New York. The plant will have a capacity of no less than 3,000 hp and consists of five 600-hp Crossley two-cylinder horizontal gas engines to be belted to alternating-current electric generators of 350-kw capacity each. The electric generators were built by the General Electric Company. Power will be generated for transmission to a group of copper, silver and lead mines, including the famous Copper Queen property and the Teneras & Santa Maria mines. The transmission line is about 50 miles long. The voltage is 13,000.

A contract has been secured for the installation of a 300-hp plant for the purpose of lighting Newton, N. J. There will be two American Crossley two-cylinder horizontal gas engines of 200-hp and 100-hp capacity respectively. These machines are to be direct-connected to 150-kw and 75-kw alternating-current electric generators.

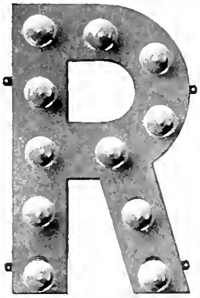
Convention of National Electrical Contractors' Association.

A special train will leave the Grand Central Station, New York, at 1 p.m. September 10, for St. Louis to convey the delegates to the fourth annual convention of the National Electrical Contractors' Association of the United States, which will be held in St. Louis September 14, 15 and 16. The train will arrive at St. Louis next evening at 6.45 o'clock. On account of the exceedingly low rates issued by the several passenger associations between St. Louis and other points it has been unnecessary to secure a special rate on the certificate plan for the benefit of delegates and visitors to the convention. The headquarters for the Eastern delegates will be at the Washington Hotel, which is within easy distance of the fair grounds. Mr. Alex Henderson, 527 West Thirty-fourth Street, New York, is master of transportation, to whom communications should be addressed.

Electrically Illuminated Roof Signs.

The desire to attract customers or to impress a firm's name or the character of a business on the inside of the public cannot be met better than with an electric roof sign, which, while it may cost from 50 cents to $5 an hour in operating expenses, is bound to be read by all the people who pass within a number of blocks, and, possibly, if it be a large sign, within a number of miles of the lôcality where the sign is placed.

The exposed position of such signs calls for solid metal construction. Such signs in all sizes have been designed and are constructed by the Haller Machine Company, of Chicago. The letters they make are indestructible and perfectly water-proof. The company is glad to furnish data as to what the operating expenses of such a sign would be. Any local electrician can connect the sign to service wires, and electric light companies are usually prepared to furnish low special rates for current for this purpose.

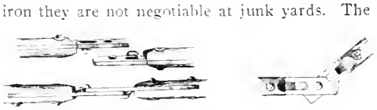


ROOF SIGN.

Underground Conduit Rods.

Since the original appearance of screw joint couplings many designs have been put upon the market and a new one is found in the "Security Conduit Rod."

The design is simple and not likely to get broken in a wagon or in a manhole. This is important, because the handling is severe. Made of iron they are not negotiable at junk yards. The joint with the wood is made by rivets holding large washers; the wood, being hickory, does not split easily, and there is no chance for a break. Coupling and uncoupling is done very quickly, and when in the duct there is no slack between joints, nor can they possibly uncouple, although they will lend themselves to moderate bends.



CONDUIT RODS.

In weight they are light, and long runs can easily be handled by one man. The standard lengths are three and four feet. The rods are easily handled in manholes, quickly jointed and unjointed, and will stand abuse. The couplings lock together rigidly and the rods will not buckle under pressure nor bind against conduit walls. There is no slack between rods. These rods are the product of the Bissell Company, Toledo, Ohio.

A Large Transmission Cable Order.

The Mexican Light & Power Company, Limited, of Montreal, Canada, recently placed with the Ansonia Brass & Copper Company, 99 John Street, New York, an order for copper cable for transmission, which is probably the largest single order for transmission cable ever placed. The order calls for 1,500 miles of cable, equal in carrying capacity to 3/0 B. & S. gauge, and weighing approximately 4,200,000 pounds. The cable is to be used on the Nicaxia-Mexico power transmission line, now under construction, and it will be supported on steel towers in spans of 500 ft. The length of the spans, together with the necessity of reducing the dip as much as possible and the high wind pressure to be withstood, made the matter of cables one of considerable importance. The cable furnished by the Ansonia Brass & Copper Company was designed by Mr. W. G. Clark, of Seattle, Wash., electrical engineer. Mr. Clark found that the cable should have the highest possible elastic limit to withstand the strain; high conductivity to reduce to a minimum the area exposed to wind pressure, high ductility to reduce the possibility of the strands breaking at the ties, and also that each length of cable should be made without splices in the strands to maintain an even temper and elongation; while the cable should be made in lengths as great as could be conveniently handled on the ground, and so designed that the strain should be evenly distributed between the constituent strands—each strand carrying its own portion of the load. A series of experiments demonstrated that while the ordinary concentric laid cable did not meet these requirements, the cable designed by Mr. Clark met the conditions in a satisfactory manner.

FIG. 1.—SHOWING METHOD OF SPLICING.

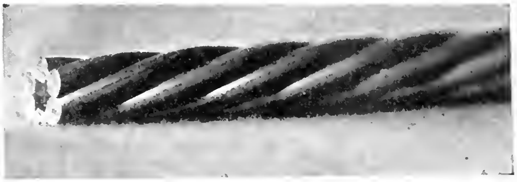


FIG. 2.—ELASTIC CENTERED CABLE.

FIG. 3.—SPLICE OF ELASTIC CENTERED CABLE.

The wires composing the cable receive a special treatment, both while the rod is being rolled and while the wire is being drawn. To secure a high elastic limit without sacrificing ductility and conductivity the cable is laid up of six wires around a soft compressible center, which is compressed as the cable is laid up, and still further compressed when the cable is placed under tension on the line. As all the strands are of equal length, compressing the elastic core, the strain is evenly distributed between the strands. After the cable is stretched in position, the core is no longer of service, and may decay or be removed without affecting the even distribution of the load. The core is so compressed that the space taken up by it is of no importance, but it materially increases the flexibility of the cable, making it more convenient to handle during erection.

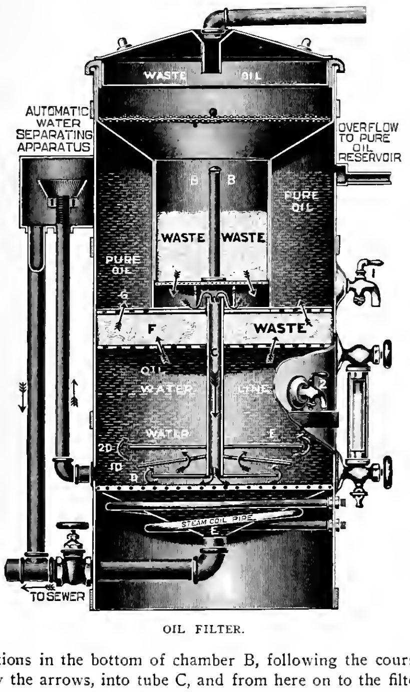
The splices in the line will be made by passing the ends of the cable through a copper tube, driving a taper pin in each end to replace the soft core, and then twisting the sleeve. A joint 12 in. in length made in this way shows one-fourth the resistance of an equal length of cable, and the wires are so firmly compressed into the copper tube that they are not affected by corrosion.

Some idea may be gained of the size of this order when it is considered that the cable, in a single length, would reach half way from New York to Seattle, Washington. The wires composing the cable, each almost as large as an ordinary lead pencil, would, if connected in a continuous length, reach entirely through the earth at the equator, with a thousand miles over; or would reach practically from New York to Manila. The reels required for shipping the cable would, if piled lying flat upon one another, make a pile 7,400 ft. high, or almost a mile and a half.

Oil Filter for Large Plants.

The Burt Manufacturing Company, Akron, Ohio, is the manufacturers of the oil filter shown in the accompanying sectional view, designed to receive the condensation from oil separators or exhaust heads and to automatically separate the oil from the water, while at the same time purifying it. The water is drained to the sewer and the pure oil, rising into a separate chamber, overflows into the pure oil reservoir. The filter is made in twelve different sizes, with filtering capacities of from 300 to 500 gallons per 24 hours.

The mixed oil and water is received through the inlet at the top of the filter and then passes through a layer of waste, which collects all the heavier impurities of the oil. Thence it passes through the



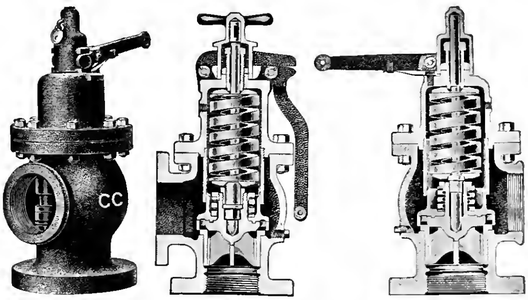
OIL FILTER.

perforations in the bottom of chamber B, following the course indicated by the arrows, into tube C, and from here on to the filter plate D. The increased weight of the water has a tendency to keep the oil back in tube C, but when the pressure of the oil in chamber B becomes sufficient the oil is forced down and spreads over the plate D in a very thin film. This constantly changes surface and grows thinner as it travels from the center to the circumference of plate D, thus exposing every particle of oil to the action of the water. It then flows on to plate 1D and 2D, going through the same process in each case. When the oil leaves the plate 2D it is in a finely divided state and is thoroughly washed by the water. It is separated from the water by gravity, and all the remaining impurities settle in chamber E, from which they can be drained to the sewer by opening the gate valve at the bottom of the filter. From the plate 2D the oil rises and again filters through F, another layer of waste, into the pure oil chamber, where it accumulates until it overflows into the oil reservoir. The water is automatically separated after it passes down the tube C and reaches the bottom plate, on account of its being heavier than the oil, and the surplus water passes into the pipe leading to the automatic water separating device.

Pop Safety Valves.

The constantly increasing demand for Crane patent "pop" safety valves has made it necessary for the Crane Company, Chicago, to increase the capacity of its manufacturing departments on these goods. It has also brought out a number of improved forms of pop valves for stationary, marine, locomotive and portable boilers; also a variety of cylinder reliefs, water reliefs, high-pressure and hydraulic relief valves for all purposes and pressures.

The construction of these valves embodies a self-adjusting feature which automatically regulates the "pop" of the valve or maintains the least waste of steam between the opening and closing points, an improvement which will be readily appreciated, as there is no necessity of re-adjusting to regulate the pop on changes in the set pressure.



POP SAFETY VALVES.

In all pop safety valves it is necessary to have a "pop" or "huddling" chamber into which the steam expands when the main valve opens, thereby creating an additional lifting force proportionate to this increased area and greater than the force of spring, thus holding the valve open until pressure is relieved. Means must also be provided to relieve this "pop" chamber of pressure, in order to allow the valve to close promptly and easily. This is accomplished by the self-adjusting auxiliary valve and spring, which are entirely independent of the main valve and spring. The steam in the "pop" chamber finds a passage through holes or ports into an annular space provided in the auxiliary valve or disc, and by reason of the light auxiliary spring this pressure lifts the auxiliary valve and allows the steam in the "pop" chamber to gradually escape, thus permitting a greater range in setting pressures with the least waste of steam and at the same time supplying a cushion or balancing medium, thereby preventing any chattering or hammering and affording the easiest possible action in closing.

The encased spring valves are constructed with a casing or chamber enclosing both springs, protecting them against the action of the steam, particularly high pressure, which, blowing with great force and velocity throughout all parts of valve before reaching the atmosphere, would otherwise have a tendency to disarrange the springs and other parts operating in connection therewith. This form of valve is also particularly useful where a number of valves may be connected to one main exhaust or discharge pipe. The encased spring chamber, extending over a greater portion of the top surface of the main valve, prevents any retarding action of the steam due to back pressure, which might be caused by one or more valves opening slightly in advance of another, in having any material effect on the free opening of the other valves.

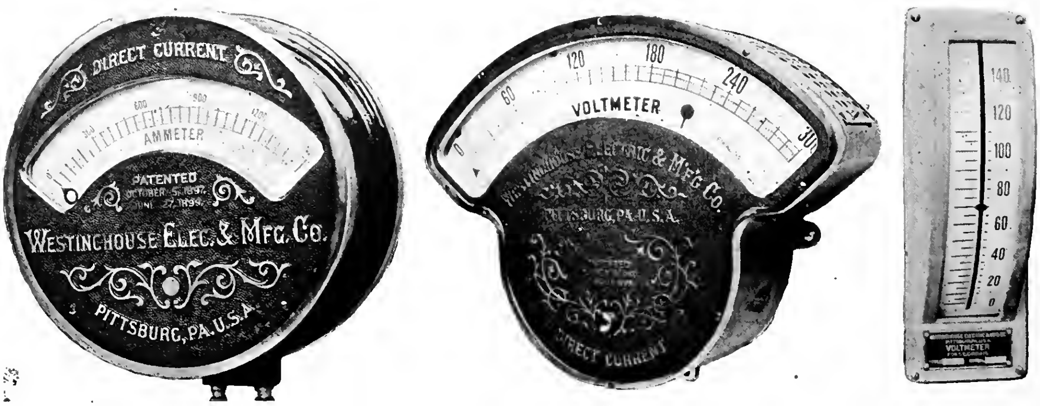
Direct-Current Switchboard Instruments.

The accompanying illustrations show a line of direct-current switchboard instruments, possessing new and novel features in their design, and which have recently been adopted for use in many high-class installations where the best of everything is required.

Three general styles are shown, the principles of operation being the same in all, but the cases and general construction differing to conform to the requirements of service. The type shown in Fig. 2 is furnished with a round case, that of Fig. 2, with an illuminated dial, and Fig. 3 is an edgewise pattern having a narrow case as shown in the illustration. All cases are dust-proof and their appearance is ornamental in effect.

In shape, size and general appearance, the instruments of Fig. 1, known as type D, correspond with the other round pattern switchboard instruments manufactured by Westinghouse Electric & Manufacturing Company. The scale is longer than that of any other similar instrument, and the divisions, which are spaced uniformly throughout, are large and open. The instrument shown in Fig. 2, known as type E, has two tabular lamps, which are so arranged in a separate ventilated compartment as to give a uniform distribution of light over an opal glass scale 20 in. in length.

The width of the cases in the edgewise pattern, known as type H, is only 5¼ in. This permits more instruments to be mounted side by side than is possible with the round pattern, when space is limited. The angle or position of the scale and the large open markings facilitate accurate readings.



Figs. 1, 2 and 3.—Direct-Current Switchboard Instruments.

In construction, these instruments combine a strength which will enable them to withstand rough usage, and a sensitiveness necessary for reliable indications. The magnetic system consists of two permanent horseshoe magnets bolted to a pair of parallel soft-iron pole pieces, the lines of magnetic force passing across the air-gap between the upper and the lower pole pieces. Enclosing the upper pole piece, but not touching it, is a movable coil of fine wire wound around an oblong aluminum bobbin. This coil is attached to the framework of the movement and its weight is just sufficient to counterbalance the weight of the pointer. This construction allows a very long scale and also permits the removal of the movement without taking off the magnets. The indications are dead-beat.

The pole pieces are attached to the permanent magnets before they are magnetized and aged and there is, therefore, no possibility of the magnetic condition being disturbed in assembling or repairing. They are kept in stock for a long time after the treatment is finished and any magnets which upon final test show change of magnetic properties, are rejected.

The controlling springs are not supported by the movement as is usual in other instruments, but are mounted on stationary brass rods in the ends of which the sapphire jewels are set. This arrangement materially reduces the weight on the pivots and in conjunction with the light weight of the moving element (which is made entirely of aluminum) and the excellence of the bearings, in which pointed steel pivots rest in the finest sapphire jewels, free the instruments from any influence by friction.

The ammeters operate from shunts made from resistance metal having a very low temperature coefficient and arranged for connection to the bus-bars. A record of the resistance of each is kept on file as well as sent with each meter, so that when an ammeter is to be calibrated or replaced by a new one, it is not necessary to disturb the bus-bars. In order to calibrate one of these ammeters, it is only necessary to connect a portable millivoltmeter in parallel across the same shunt.

Electric Automobile Charging Panel.

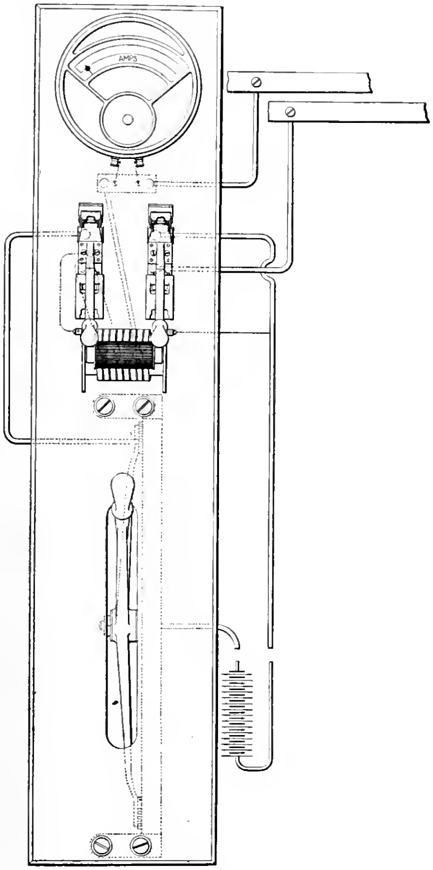
The wide application of storage batteries as a source of power for electric trucks and automobiles, has brought forward the matter of battery protecting devices best suited to the requirements of this class of service. On the manner in which the storage battery is handled, largely depends the successful or economic service of the electric vehicle. If the battery is charged at too high a rate—that is, the charging current is too great—the plates of the battery are destroyed; while a discharge of the battery under abnormal conditions will also cause serious damage to the battery. Careful attendants, guided by suitable measuring instruments, will minimize these dangers, but what is desired is an automatic device which will protect the battery in case of any abnormal condition.

The accompanying illustration is of a standard electric automobile charging panel; on it is mounted an ammeter, a rheostat and an overload and reverse-current circuit-breaker of the "Dublarm" type, which acts as a combined hand switch and circuit-breaker.

The ammeter shows the current flowing into the battery and can be supplemented by a voltmeter which would show the voltage; but, where a number of these panels are used, one voltmeter on a swinging bracket at the end of the board usually serves for all the feeders. The rheostat in series with the line varies the voltage of the charging circuit and in that way allows the charging current to be either increased or diminished as required while the battery is being charged.

The circuit-breaker acts as the main feeder switch, and is so designed that it automatically opens the circuit the instant the charging current exceeds an allowable amount. It is provided with a calibrated scale, which can be adjusted so that the circuit-breaker will open at any desired current, and also automatically open in case the current should flow from the battery into the charging circuit, which would discharge the battery and possibly ruin the plates. Both the overload and the reverse current features are absolutely positive in their operation.

This circuit-breaker is made by the Cutter Company, of Philadelphia, and is one of their "Reversite" types, which have been very largely used by the United States Navy for the protection of storage batteries used in connection with their naval telegraph equipments. They are also used extensively for the protection of



CHARGING PANEL.

storage batteries in telephone exchanges, and are made single, double and triple-pole in any capacity to meet the various requirements.

Measuring Currents in Cables.

A simple apparatus for measuring the current at any point of a cable and thereby determining the load on a feeder or at a point of a distribution network, is shown in the accompanying illustrations, the apparatus being made by the General Electric Company. It consists of a special transformer having a hinged magnetic circuit and a standard Thomson inclined coil ammeter.

The magnetic circuit of the transformer is of specially treated iron thoroughly laminated and accurately machined. Special attention has been given to the hinged and clamping joints so as to insure the best possible magnetic path. The former is provided with a strong and easily manufactured locking device, which insures a uniform and positive contact. The transformer windings, which are placed on either arm of the hinged magnetic circuit, are of 5 amp. capacity and designed to withstand 2,300 volts potential between the windings and core. High insulation is secured by winding the coils on heavy insulation wrapped around the hinged iron core, and is further safeguarded by thoroughly impregnating the windings with a special insulating compound.

In order that the serviceableness of the testing outfit may be further increased, flexible duplex leads 40 ft. in length are supplied with each set. The transformer can thus be clamped in position around the conductor and the ammeter removed to a more convenient place for reading. The ammeter is constructed so as to withstand the hard usage to which portable instruments are subjected. Each instrument is provided with an armature locking device, which, when the instrument is not in service, lifts the pivots from the jewels and prevents damage to these parts. In order that accurate and rapid read-

FIG. 1.—TRANSFORMER WITH PORTABLE AMMETER.

ings may be taken, the instrument is provided with a damping device, which enables the indicating pointer to be brought quickly to rest after each change of current. The scale is satisfactory as to length, legibility and distribution—a fact of much importance in making tests covering wide ranges of current.

When a test is to be conducted the terminals of the duplex leads

FIG. 2.—TRANSFORMER OPEN.

should be inserted in the ammeter binding posts and the transformer jaws firmly clamped in position around the cable. The transformer will maintain within commercial limits its ratio accuracy from one-eighth load to 25 per cent. overload. The combined weight of the transformer and ammeter is about 25 pounds.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—The stock market was extremely dull with alternating periods of depression and slight rallies on short covering. Trading was narrow, the inactivity of business and the unsettled crop outlook tending to create some bearishness. Features were lacking, the principal trading having been in the Steel shares, Consolidated Gas and Erie, with alternating weakness and strength. Reports were heard that Brooklyn Rapid Transit is likely to show largely increased earnings during the summer, but they had no visible effect on that stock. Amalgamated Copper was the object of a certain amount of trading, but with negative results. Among the industrials, Allis-Chalmers common kept steady at 6 throughout the week, which figure was also the closing price. Preferred closed at 39¾, a net gain of ¼ point. General Electric lost 2 points in the week's trading, the prices ranging between 153 and 156¼, the closing quotation being 155. Westinghouse made a gain of 1⅛ points net, closing at 156⅛. The traction stocks were firmer and all closed with net gains. Brooklyn Rapid Transit closed at 46⅜, a gain of ⅝ point; Metropolitan Street Railway at 111, a gain of ¼ point, and Manhattan Elevated at 142½, a gain of 1 point. Western Union lost ¾ point, closing at 87¼. Outside securities were heavy as to prices and transactions were limited. Interborough Rapid Transit closed at 112, after having declined to and recovered from 106⅜, the closing figure being a net gain of 4½ points. Following are the closing prices of May 24:

BOSTON EDISON.—A Boston dispatch to the *Wall Street Journal* says: "By the payment May 2 of the final instalment on its new stock, the Edison Company has taken up about $500,000 of its notes, leaving at present $1,000,000 still outstanding. These notes are of various maturities, the longest being for a year, and the latter bearing a 4 per cent. interest rate. Additional notes of about $1,000,000 will be issued between now and next winter, when a 10 per cent new stock issue will be made, which will clean up the entire floating debt. The Edison Company has not yet taken over the electric business of the Woburn Electric Company, owned by interests friendly to the former company. The electric business of the Chelsea and Newton & Watertown gas and electric companies also has not been taken over. These companies are owned by interests representing the Edison Company and Massachusetts Gas Companies. With the Bay State gas suit now settled, it is expected that early action will be taken to assimilate these properties, the gas business in each instance going to the Massachusetts Gas Companies and the electric business to the Edison Company.

KINLOCH TELEPHONE IN ST. LOUIS.—It is stated that financial arrangements have been completed by the Kinloch Long Distance Telephone Company of Missouri with a St. Louis banking syndicate, whereby it, together with other leading independent companies of the country, will be enabled to perfect a trans-continental long-distance system. The Kinloch Co. will shortly file a first mortgage deed of trust to the Mississippi Valley Trust Company, of St. Louis, trustees, covering all of the suburban and interurban properties embraced in the long-distance service. The deed of trust will secure an issue of $5,000,000 first mortgage 5 per cent. 25 year old gold bonds, dated 1904 and maturing in 1929, and the specific purpose of the mortgage is to provide additional capital for extra outlays needed for additions, extensions and other like improvements. It is the intention to eventually gridiron the southwest with lines and with the co-operation of half a dozen of the largest companies not allied with the American Bell Telephone Company, a powerful organization is expected.

COLORADO TELEPHONE.—The Colorado (Bell) Telephone Company reports as follows for the year ending December 31, 1903, and preceding years:

	1903.	1902.	1901.
Gross	$1,294,837	$1,083,037	$858,820
Expenses	977,733	771,231	625,956
Net	$317,104	$311,806	$232,864

The company's capital stock on December 31 was $4,153,000, an increase of $753,550 over 1902. The number of subscribers stations is now 30,226, an increase of 6,753 over 1902. Of the expenditures of $977,733, $289,211 or 29.6 per cent. was charged to maintenance. The American Telephone and Telegraph Company on June 30 last owned $1,744,250 of the $3,400,000 capital stock or 51 per cent.

NEW ENGLAND TELEPHONE.—The New England Telephone and Telegraph Company will in all probability issue additional stock this summer for new construction. It has been the custom of the company for several years to issue additional stock annually, but the rule was broken last year, as the financial conditions were not propitious for a new stock issue and the company was well provided with funds. The growth of the company's business, averaging about 15,000 new subscribers annually, requires about $2,000,000 new capital each year for new construction. For the first three months of this year there were 4,000 new subscribers added, making total subscribers March 31, 130,138. The last new stock was issued in June, 1902, stockholders being offered 36,047 new shares at par on the basis of one new share for each five owned.

THE CALIFORNIA GAS AND ELECTRIC CORPORATION held its annual meeting in San Francisco on April 3. The first monthly dividend of 25 cents per share was declared payable May 16. It was decided to set aside $1,000,000 for betterments and extensions during the coming year. Additional electrical machinery will be installed to operate the Sacramento Electric Gas and Railway Company's system. A large amount will be expended on improving the Standard Electric transmission system, which was recently acquired. An additional 4,000-kw generating unit will be installed this summer at the De Sabla power station.

NIAGARA FALLS POWER REPORT.—The Niagara Falls Power Company reports as follows for the six months ended December 31, 1903: Gross, $579,550; net, $481,060; other income, $37,296; total net, $518,356; surplus after charges, $144,416; improvements, betterments, etc., $42,199; surplus, $102,217. Fixed charges, taxes, etc., include interest for six months on $10,000,000 first mortgage bonds, and on the 6 per cent. debentures issued for the construction of power house No. 2 and one-half of all taxes for the year. Surplus for the six months amounts to about 4 per cent. on the outstanding stock.

NORTH AMERICAN IN ST. LOUIS.—The Laclede Gas Light Company sold recently to N. W. Harris & Co., $4,000,000 5 per cent. 30-year bonds, which has enabled it to pay off the short time notes issued a few months ago, besides giving abundant funds for all purposes. N. W. Harris & Co. sold the entire issue, mostly in the West, before the bonds could be engraved. The North American Company now has its new power plant at St. Louis practically completed, the engines having been installed, and is ready to furnish power to the St. Louis car lines.

CHARLESTON GAS AND ELECTRIC.—The Consolidated Railway Gas and Electric Company, of Charleston, S. C., for year ended February 28, 1904, showed gross $538,173, and surplus after expenses, fixed charges, sinking fund, etc., $22,161.

SOUTHERN ILLINOIS TROLLEYS.—It is stated in Chicago dispatches that the Southern Illinois Electric Traction Company has voted an increase in capital stock from $50,000 to $2,000,000. An extensive system of electric railroad is to be built in the vicinity of Mount Vernon, Ill.

MISSOURI BELL TELEPHONE.—The Bell Telephone Company of Missouri has been given authority to increase its capital from $4,000,000 to $10,000,000 for the extension of its business and system.

BUYING WIRELESS PATENTS ABROAD.—A cable dispatch from London states that a syndicate represented by Charles J. Glidden and E. Bertram Newton, of Boston, have purchased the rights to use the Armstrong-Orling wireless telegraph and telephone patents in the United States and Republic of Mexico. This system has been illustrated and described in our columns. Mr. Glidden is a veteran telephone manager and financier, prominent formerly in the Erie Telephone & Telegraph Company.

BONDS FOR POWER PLANT.—The St. Joseph and Elkhart Power Company has filed a mortgage of $1,750,000 to the New York Security and Trust Company, to secure a bond issue.

Commercial Intelligence.

THE WEEK IN TRADE.—Complaint is still heard of unseasonable weather, trade and the crop situation being affected thereby. According to reports received by the mercantile agencies cool weather is responsible for the slow distribution of spring and summer goods at retail, and the retardation of germination and growth of crops, though permitting good progress in seeding in various sections of the country. In jobbing circles there appears to be a feeling that the spring trade is past, and efforts are now being concentrated on fall business. The industrial situation is somewhat quieter. The strike of masters and pilots of lake vessels continues, with no prospect of settlement. This has had a serious effect on lake transportation. No expansion is indicated by bank clearings, which are considerably behind those of last year. Railway earnings show losses as compared with last year. For the first half of May the decrease in gross is about 4 per cent., and the same percentage of loss is shown for the entire month of April. For the first three months of the year gross earnings are about 1 per cent. less than last year, and net receipts are about 15 per cent less. Money is still easy, but collections are backward. The iron market showed most pronounced weakness, declines ranging from 25 to 50 cents per ton. Among the finished products bar iron is lower at the west, but steady at the east. The other metals are all weaker, copper being dull and heavy at a slight decline. Two hundred and fifteen business failures during the week ended May 16 are reported by *Bradstreet's*, an increase of 14 as compared with the previous week. During the corresponding week last year the number was 155.

BELL TELEPHONE OUTPUT.—The instrument statement of the American Telephone & Telegraph Company for the month ended April 30 and since December 20 is as follows:

	1904.	1903.	1902.	1901.
Gross output	102,907	104,429	108,242	72,396
Returned	42,335	43,491	37,587	33,177
Net output	60,572	60,938	70,655	39,219
Since December 20:				
Gross output	404,475	410,390	387,795	288,505
Returned	151,325	160,137	152,085	122,604
Net output	253,150	250,253	235,710	165,901
Total outstanding	4,032,667	3,400,573	2,761,720	2,118,717

The above statement shows a net output of 60,572, bringing the total number of instruments outstanding for the first time in the company's history above the 4,000,000 mark. The number outstanding on April 30 was 4,032,667, which compares with 3,779,517 outstanding at the close of 1903. The extremely rapid growth of the Bell system apparently shows no signs of let up. The growth in the four months ending April 30, as shown by the net output of 253,150 instruments, is equal to 6½ per cent., or at the rate of 2 per cent. a year. If this rate is continued, the system will have 4,500,000 instruments outstanding by next December. Five years ago the system had 1,125,000 instruments outstanding, and ten years ago it had less than 600,000. The increase in five years has amounted to nearly 300 per cent.; and in ten years to nearly 600 per cent. It will of course be understood that the number of instruments has to be divided by two to get at the actual number of stations.

HUGE PLANT FOR PHILADELPHIA WANAMAKER STORE.—The new Wanamaker department store under construction in Philadelphia is to be equipped with one of the largest, if not the largest, isolated electric lighting plant in this country. While no definite details are available at the moment, it can be said that the capacity will be not less than 3,000 kw. The boilers have already been contracted for with the Babcock & Wilcox Co., New York. The boiler capacity will he 5,300 hp. The Philadelphia store has been designed by D. H. Burnham & Co., of Chicago. Charles Wilks, the Burnham Co.'s chief engineer, is now engaged in drawing up the plans for the electric plant. The contracts for equipment will in all probability be awarded through H. D. Babbit, the electrical engineer of the Thompson-Starrett Co., which concern will construct the building. Mr. Babbit is an old Chicago Edison man. The new Wanamaker store being built between Eighth-street and Broadway, New York, by the same contractors, is to have an 1,800 kw plant, Westinghouse generators and Buckeye engines having been ordered last month. Figures on the Philadelphia plant are expected to be taken in about a fortnight.

INSULATED WIRE FOR JAPAN.—The Safety Insulated Wire and Cable Company, 114 Liberty Street, New York, has received a contract from the Japanese Government contracting firm of Oki & Co., Tokio and Yokohama, for a very large lot of rubber insulated wire. The Artillery Corps, which arm of the United States army has just taken over the submarine mining and coast defense work from the engineering corps, has contracted with the Safety Insulated Wire and Cable Company for a big lot of torpedo cable. The Artillery Corps headquarters are at Willets Point, N. Y. Captains Bailey and Parker are the senior officers. The company has also been awarded the contract for laying the Commercial Cable Company's land cable between Coney Island and 20 Broad Street, New York.

CONTRACT LET FOR 1,000 H. P. MEXICAN HYDRAULIC PLANT.—The electrical engineering and contracting firm of Ugarte & Garcia, Guadalajara, State of Jalisco, Mexico, whose representative, Mr. Ugarte is now in the State, being at the time of writing in St. Louis, has secured a contract for the construction and equipment of a water-power plant of 1,000 hp capacity. The equipment will include three alternating-current generators of 250 kw capacity each for direct connection to water turbines. The transmission line will be about 15 miles long. The equipment, etc., will be manufactured in the United States and the plant is expected to be in running order inside of 12 months.

FEEDER CABLE, ETC., FOR MANILA.—The electrical engineering and contracting firm of J. G. White & Co., New York, which concern has the contract for the construction and equipment of the extensive electric lighting and traction system now being hastened to completion on behalf of an American syndicate at Manila, has awarded contracts for a big lot of triple braid weather-proof feeder cable to the Holmes, Booth & Haydens Co., New York, while the Magnet Wire Company, New York, secured the substantial order for the bare magnet wire.

EQUIPMENT FOR HENRY HEIDE ADDITIONAL PLANT.—An extensive addition is to be made to the candy manufacturing plant of Henry Heide, at Vandam and Hudson streets, New York, which will be equipped with a large-sized electric plant. Mr. C. O. Mailloux, New York, will act as consulting expert regarding the matter while Mr. C. J. Goldmark, of New York, will be the electrical engineer. Plans are now being drawn up and figures will be taken next month.

EQUIPMENT FOR CENTRAL PARK APARTMENTS.—The equipment to be installed in the addition of the Central Park apartment house at Seventh Avenue and Fifty-eighth St., N. Y., has been ordered. There will be a 450-hp outfit. Mackenzie, Quarrier & Ferguson, 114 Liberty Street, secured the contract, which calls for three 150-hp Harrisburg engines direct-connected to General Electric generators of 100-kw. capacity each.

EQUIPMENT FOR NEW BUENOS AYRES THEATRE.—A large electrically operated heating, ventilating and cooling system is to be installed in the $2,000,000 Colon Theatre building now under construction at Buenos Ayres, Argentine Republic. The contracts will be placed in the United States through the export commission house of Kates & Bok, Orient Building, Wall Street, New York.

EQUIPMENT FOR PORTO RICO SUGAR PLANTATION.—M. G. F. Tremain, 135 Broadway, New York, has secured a contract for a Robb-Armstrong engine, built by the Robb Engineering Company, of Amherst, Nova Scotia, for belting to a generator. The outfit will be used for light and power purposes on a large sugar plantation located in the vicinity of Mayaguez, Porto Rico.

EQUIPMENT FOR MICHOACAN MINES.—The Carrizal Gold Mining Company which operates extensive mines in the State of Michoacan, Mexico, will shortly let contracts for the construction and equipment of a fair-sized electric plant. Mr. S. L. Butler, of Salt Lake City, Utah, is president of the company.

BIG STORAGE BATTERY OUTFIT FOR MEXICO.—The Compania Minera de Penoles which Mexican concern operates extensive mines at Mapimi, State of Durango, already equipped with considerable American electrical machinery, is about to install a large storage battery outfit for the smelter plant.

NICARAGUAN POWER TRANSMISSION.—The Siempre Viva Mining Company, of Bluefields, Nicaragua, Central America, is having plans drawn up by Wallace C. Johnson, consulting engineer, Niagara Falls, N. Y., for the construction of an extensive power transmission system.

EQUIPMENT FOR ERIE BASIN IRON WORKS.—The Erie Basin Iron Works, which are controlled by the Krawjenski-Pesant

Co., sugar machinery manufacturers, New York, is to be equipped with considerable electrical equipment, including an alternating-current crane.

THE FIBRE CONDUIT COMPANY, Orangeburg, N. Y., reports that between April 1, 1903, and April 1, 1904, the number of orders received has increased nearly 300 per cent., and the month of April, 1904, is the largest April in the history of the company, including orders from Electrical Commission of Baltimore, Md.; Edison Electric Illuminating Company, of Brooklyn, N. Y.; General Electric Company; Merchants' Heat & Light Company, of Indianapolis, Ind.; Cazenovia Light & Power Company, of Cazenovia, N. Y.; Westinghouse Electric & Manufacturing Company; Suffolk Light, Heat & Power Company, of Southampton, N. Y.; United States Naval Academy, of Annapolis, Md.; Edison Electric Illuminating Company, of Detroit, Mich.; Morton F. Plant, of Groton, Conn.; Citizens' Telephone Company, of Grand Rapids, Mich.; Edison Electric Illuminating Company, of Boston, Mass.; Public Service Corporation, of New Brunswick, N. J.; W. M. Sheehan Company, of New York City; Telluride Power Company, of Provo, Utah. Most of the above companies are old customers, and it certainly speaks well of the product to have them come back every year. The Telluride Power Company at Provo, Utah, is building an underground conduit system for its 60,000-volt circuits and sent its representative East to investigate with the result that its entire order was placed for fibre conduit. The Electrical Commission in Baltimore has used approximately half a million feet and still continues to send orders.

SOME HARRISBURG ENGINE ORDERS.—Mackenzie, Quarrier & Ferguson have secured a contract for a 125-hp Harrisburg standard engine for direct connection to a 75-kw. Crocker-Wheeler generator as additional equipment for light and power purposes in the Philadelphia plant of the Pennsylvania Salt Company. Ten 125-hp Harrisburg standard engines have also been ordered for direct connection to 75-kw. Northern generators. This equipment will be installed in the Twenty-third Regiment Armory, Brooklyn, for lighting purposes. A 75-hp Harrisburg standard engine direct-connected to a Crocker-Wheeler generator has been ordered as an additional unit for the State Normal School at Trenton, N. J. Among foreign contracts in hand is one for a 100-hp Harrisburg engine which is to be belted to a 62½-kw. generator of General Electric build for shipment to Newcastle, Australia.

STERLING ELECTRIC COMPANY, Lafayette, Ind., has just received large orders for telephones from the following cities: Hudson, N. Y.; West Liberty, Iowa; Redkey, Ind.; Ossian, Ind.; and Cedar Rapids, Iowa—the latter for its four party line selective type of telephones. It is installing its latest type of combined distributing boards and protectors at Ames, Iowa; Caro, Mich., and Sully, Iowa. It has also contracted for a 500 tubular drop, bell type switchboard for Eaton, Ohio. It has also received orders for various switchboards and additions for Monticello, Ind.; Brandenburg, Ky.; Mattoon, Ill., and Galena, Kan. In addition to this, it has received large orders for its various types of protectors for Kansas City, Mo.; Peru, Ind.; Pittsburg, Pa.; Hudson, N. Y., and Lyons, Iowa. It has been recently reported that the Sterling Company is receiving orders for condensers of its manufacture at a rate of 5,000 a day.

ELECTRIC POWER FOR DIAMOND MATCH COMPANY.—The Diamond Match Company, which is building several large factories in and near Chico, Cal., has closed contracts through the Wagner-Bullock Electric Company, of California, for three alternating current generators to supply electric power for operating woodworking machinery. There will be three generating units, each consisting of a Bullock generator direct connected to an Allis-Chalmers automatic engine. Sterling boilers will be installed in the power station. The distance of transmission will be short.

THE S. H. COUCH COMPANY, of Boston, Mass., has recently closed several contracts for telephone equipment, among which are the Lafayette Hotel, Portland, Me., which calls for 140 telephones and a 140-line common battery board of its new target type. This replaces a previous equipment recently installed. Also orders for common battery boards for Worcester City Hospital, Worcester, Mass., replacing present system, and Hartford Carpet Corporation, Thompsonville, Conn., and a magneto board for Medfield Insane Hospital, Medfield, Mass.

WALRATH GAS ENGINES FOR PORTUGAL.—The Marinette Gas Electric Company, of Chicago Heights, Ill., has secured a contract for five double cylinders Walrath gas engines for direct connection to generators. This contract came from Portugal. The equipment will be used for lighting purposes. A 75-hp three-cylinder engine direct-connected to generator was recently shipped to Lisbon, Portugal, for installation in the building occupied by the Bank of Portugal where several other Walrath engines are installed.

EQUIPMENT FOR LIMA LIGHTING PLANT.—The Compania Santa Rosa, Limitada, which concern lights Lima, Peru, is to extend considerably its water power plant. The General Electric Company has taken the order for the generator, which is to be of 800-kw capacity. The water wheels will be shipped by the Pelton Water Wheel Company, which has also taken an order for 2,100 ft. of 60-in. pipe. The existing equipment consists of three 400-kw General Electric generators and Pelton wheels.

THE EDISON ELECTRIC COMPANY, of Los Angeles, Cal., has recently placed an order with the Abner Doble Company, of San Francisco, for two 800-hp, 176 r.p.m. impulse water-wheels, two 40-hp exciter wheels, and two type F Lombard governors. These wheels will be installed in the Edison Company's Santa Ana River No. 2 plant near Redlands, and will operate under a 305-foot head. They will be connected to General Electric 750-volt three-phase generators.

LARGE SWITCHBOARD EQUIPMENT.—The H. Krantz Manufacturing Company, of Brooklyn, has secured the contract for the switchboard, etc., to be installed in the electrical plant of the Metropolitan Life Building, Madison Square, New York. There will be no less than 156 Dublarm type circuit-breakers, combination switch and circuit-breakers on the board. It will be the largest installation of its description hitherto contracted for.

THE AUTOMATIC ELECTRIC COMPANY, of Chicago, is now installing 4,000 automatic telephones and complete switching equipment for the Home Telephone Company of Los Angeles, Cal., and 1,200 for the Auburn Telephone Company, Auburn, N. Y. It has received orders for the equipment of San Diego, Cal., with 1,200 automatic telephones, and Lewiston, Me., with 1,500.

WESTERN ELECTRIC COMPANY'S NEW PLANT.—The Falkenau Construction Company has been awarded the contract for the erection of some more new buildings at the Western Electric Company's plant at Hawthorne, near Chicago. The principal building will be for the insulating plant and will be 401 x 200 ft. The total cost, with other lesser structures, will be about $142,000.

THE WIRT ELECTRIC COMPANY, of Philadelphia, has moved into its new factory at 3108 Germantown Ave., the change being rendered necessary by its rapidly increasing business. The new plant is commodious, well planned, and affords the company every facility for turning out high-class work promptly.

EQUIPMENT FOR HOTEL RENAISSANCE.—The Hotel Renaissance, West Forty-third Street, New York City, is to be equipped with two 100-hp Harrisburg standard engines direct-connected to 60-kw, 125-volt General Electric generators. The outfit will be used for both light and power purposes.

NEW HARMONIE CLUB TO TAKE STREET CURRENT.—There will be no plant installed in the first instance in the new Harmonie Club to be built in East Sixtieth Street, New York, as power will be taken from the street. C. O. Mailloux is the consulting engineer.

LIGHTING PLANT FOR BRAZIL.—The export commission house of Agar, Cross & Co., New York offices Bowling Green Building, representing the Westinghouse interests in Brazil, has been awarded a contract for the construction of a plant which is to light Rio VI.

EQUIPMENT FOR MEXICAN CARRIAGE FACTORY.—Electrical equipment is to be installed in a large carriage factory about to be constructed by Noake & De Smeth, Chihuahua, State of Chihuahua, Mexico.

RHODESIAN LIGHTING PROJECT.—A municipal electric lighting system is to be installed in Salisbury, Rhodesia, South Africa. Mr. Crawford Lindsay is the consulting engineer. Salisbury has a population of about 15,000 people.

EQUIPMENT FOR MEXICAN CONCENTRATOR.—Electric power is to be substituted for gas power for generating energy to operate the 450-ton concentrator plant of the Tecoletes Company, at Santa Barbara, Mexico.

HEINE BOILERS FOR WILKESBARRE.—The Wilkesbarre & Wyoming Traction Company, of Wilkesbarre, Pa., has placed a contract for a 1,500-hp boiler outfit with the Heine Safety Boiler Company, New York offices Bowling Green Building.

ELECTRIC DRILL GRINDERS FOR SOUTH AFRICA.—The Wilmarth & Moorman Company, of Grand Rapids, Mich., has secured a substantial contract for electrically-driven drill grinders for export to South Africa.

MORE EQUIPMENT FOR HENDERSON, KY., PLANT.—The plant of the Henderson, Ky., Street Railway is to be enlarged. The boiler order has just been let to the Heine Safety Boiler Company, of St. Louis.

ELECTRICAL SUPPLIES FOR CUBA.—The Robb-Mumford Boiler Company, New York, has two good-sized orders in hand for electrical supplies for shipment to Havana.

General News.

THE TELEPHONE.

LOS ANGELES, CAL.—According to a report just issued by the Home Telegraph & Telephone Company, its earnings for the quarter ended April 1 were $74,698.59 and operating expenses $47,881.08, leaving the net earnings for the quarter $31,817.51. This amount, together with $5,029.61, gives a total of $36,847.12 available for dividends or improvements. The number of instruments installed up to April 1, 1904, was 12,026. During the previous six months 3611 were put in and during the last quarter 1551 were reported.

SPRINGFIELD, ILL.—The Calhoun Telephone Company, of Hardin, Ill., has increased its capital stock from $15,000 to $25,000.

WATSEKA, ILL.—The Fountain Creek Telephone Company has been incorporated with a capital stock of $24,000. G. H. Weil is president.

BELLEVILLE, ILL.—A mortgage has been filed in Belleville by the Kinloch Long Distance Telephone Company to the American Trust and Savings Bank, Chicago, and George W. Galbreath, of St. Louis, for $5,000,000.

MONROVIA, IND.—The Monrovia Telephone Company has incorporated to build an exchange and telephone lines in Morgan and Hendricks counties. The capital stock is $2250. W. H. Hubban is president.

DELPHI, IND.—The New Co-operative Telephone Company organized in this (Carroll) county will be known as the Flora and Bringhurst Co-operative Telephone Company. The company will put in an entirely new system. Dr. W. E. Callam is president and A. G. Crosswhite, secretary.

SPENCER, IND.—The Farmers' Mutual Telephone Association has been incorporated to operate in Owen, Monroe, Morgan, Putnam, Clay and Greene counties. The capital stock is $10,000. John S. Snodgrass, John Smith, E. F. White and S. H. Alverson, are the incorporators.

BLOOMINGTON, IND.—The Bloomington Home Telephone Company has filed articles of incorporation with the Secretary of State. The capital stock is placed at $150,000. The company will establish an exchange and system of telephones and lines in Bloomington and Monroe County. J. D. Showers, W. D. Bradfute, E. L. Barber and Q. C. Mentieth are the directors.

ELKHART, IA.—The Elkhart Mutual Telephone Company has been incorporated with $10,000 capital stock.

KEOKUK, IA.—The Iowa Telephone Company has secured a lot in this city and will soon erect a building for its exchange.

WEST UNION, IA.—The Rogers Telephone Company has been incorporated with a capital stock of $25,000. The directors are C. H. Talmadge and others.

LOUISVILLE, KY.—The Deatsville & Solitude Telephone Company has been incorporated in Nelson County with a capital stock of $800.

BALTIMORE, MD.—The ordinance granting the Maryland Telephone & Telegraph Company the right to use the streets for electric light and power wires has passed the council and has been signed by the Mayor.

GRAND RAPIDS, MICH.—The Cranmoor Telephone Company has been incorporated with a capital stock of $2000. The directors are J. B. Arpin, M. O. Potter and others.

ROTHSAY, MINN.—The Rothsay Telephone Company has been incorporated with a capital stock of $10,000.

ST. LOUIS, MO.—The Bell Telephone Company, of Missouri, has been granted authority to increase its capital stock from $4,000,000 to $10,000,000. The company will improve and extend its lines throughout the State.

RED LODGE, MONT.—The supreme court of Montana, in a recent decision, held that the city council could not restrain the Rocky Mountain Bell Telephone Company from erecting poles and string wires in the city, provided the company gave the city the privilege of designating where the poles should be placed.

HARDY, NEB.—The Hardy Telephone Company has been incorporated with a capital stock of $10,000.

ARAPAHOE, NEB.—The Arapahoe Independent Telephone Company has been incorporated with a capital stock of $20,000.

RENO, NEV.—Linemen have started from Tonopah on the construction of a telephone and telegraph line to Goldfields. Poles have already been distributed, and no time will be lost in carrying the line to completion.

KEESEVILLE, N. Y.—The Keeseville Telephone Company has been incorporated with a capital stock of $20,000. The directors are J. H. A. Bond, J. B. Mace, and others.

BINGHAMTON, N. Y.—The Whitney's Point and Glen Aubrey Telephone Company has been incorporated with a capital stock of $1000. The home office will be in Glen Aubrey.

LEONARD, N. D.—A telephone company has been organized here with Richard Piper as president.

BEREA, OHIO.—The Citizens' Telephone Company has increased its capital from $40,000 to $50,000. H. E. Bolles is president.

STRYKER, OHIO.—The Stryker Telephone Company has increased its capital stock from $10,000 to $15,000 and is planning improvements to its system.

MT. VERNON, OHIO.—The Mount Vernon Telephone Company, capital $150,000, has been incorporated by J. E. Russell, W. C. Curtis, O. M. Arnold and others.

ROCK CREEK, OHIO.—The Covell Telephone Company, of this place, will build a line to connect with the exchange at Jefferson. The Covell company is building farmers' lines throughout this district.

PERRY, OHIO.—The Perry Telephone Company, capital stock $10,000, has been incorporated by F. E. Morrison, W. R. Child, J. H. Brown, E. W. Orcutt and others to build an exchange at Perry.

SUMMERFIELD, OHIO.—The Summerfield Telephone Company, of Noble County, has been chartered with $10,000 capital stock by Wm. Simmons, E. S. Wilson, H. R. McClintock, C. H. Dew, J. H. Sparling and others.

CLEVELAND, OHIO.—All of the telephone operators employed by the Cuyahoga Telephone Company on May 1 received an advance in salary about 8 per cent. President Dickson, it is stated, had the matter under contemplation for several months and strongly advocated better salaries for the employees.

CLEVELAND, OHIO.—The United States Telephone Company has closed a contract whereby after July 1 it will have an interchange of business with the National Telephone Company, of Wheeling, W. Va. The lines of the Flushing and Belmont telephone companies have been leased and these with about 25 miles of a new line will give the desired connection.

MORRISON, OKLA.—The Perryman Telephone Company has been incorporated with a capital stock of $2000. The directors are J. T. and L. Perryman and others.

ENID, OKLA.—The Garland Mutual Telephone Company has been incorporated with a capital stock of $1000. The directors are H. C. Davis, R. H. Smith and others.

ALTOONA, PA.—The Highland Telephone Company has been formed to establish a telephone line in Summerhill and Cambria townships.

ANDERSON, S. C.—The Anderson Telephone Company, manufacturer of instruments, has increased its capital stock from $16,000 to $30,000. G. W. Evans, W. R. Osborne and others are the directors.

ALPENA, S. D.—The Alpena Telephone Company has been incorporated with a capital stock of $5000.

TAYLORSVILLE, TENN.—The Smith County Telephone Company has been organized in this city and capitalized at $5000.

MEMPHIS, TENN.—The Western Union Telegraph Company has completed plans and specifications for the extension of its underground system in a large section of the up-town district in this city. The cost will be about $20,000.

COVINGTON, TENN.—The Cumberland Telephone Company has withdrawn its service from Covington a tax of $1.50 per pole having been placed on it by the city. The Memphis Telephone Company will install an exchange in place of the Cumberland.

LYTLE, TEX.—The San Antonio & Lytle Independent Telephone Company has completed its telephone line from San Antonio to Lytle.

WEBB, TEX.—The Gertie Webb Telephone Company has been incorporated with a capital stock of $20,000. J. H. Miller, A. M. Fowler and others are the directors.

DEXTER, TEX.—The Dexter & Gainsville Telephone Company has been incorporated with a capital stock of $2000. The directors are J. F. Morris, D. D. Thorn and others.

TYLER, TEX.—D. A. Walker, of Columbus, Ohio, and associates, have purchased the exchanges of the Tyler Telephone Company and the Globe Telephone Company of this place. The exchanges will be enlarged.

SEYMOUR, TEX.—The Proffitt Telephone Company, of this city, has filed letters of incorporation, with a capital stock of $40,000. The incorporators are J. W. Proffitt, John H. Proffitt, of Proffitt, W. E. Hayner and W. E. Bailes, of Seymour.

HOUSTON, TEX.—The Phoenix Telegraph & Telephone Company has been organized with principal office in this city for the purpose of building and operating telephone lines in a large number of counties of the Northern and Eastern parts of the State. The incorporators are J. M. Smith, Lorenzo Hills and A. L. Hills.

FILLMORE, UTAH.—The Millard County Telegraph & Telephone Company has been incorporated with a capital stock of $6000. Mr. Thomas A. Callister is president.

ORFORDSVILLE, WIS.—The Orfordsville Telephone Company has increased its capital from $10,000 to $15,000.

MILWAUKEE, WIS.—The Old Dominion Telephone Company, of Roanoke, Va., has been incorporated in this State.

HALIFAX, N. S.—A combination of the Nova Scotia Telephone Company, the Eastern Telephone Company, and other companies has just completed a telephone system 293 miles long. It runs from Halifax to Cape Porcupine via Truro, New Glasgow and Antigonish. Connection is made over the strait of Canso by a submarine cable, the line then runs to Sydney direct. A branch runs from Aulds Cove to Mulgrave and another from Port Hastings to Hawksbury. Connection has also been made with the Sherbrooke Telephone Company at Antigonish and with lines running to St. Peters and Narricht at Port Hawksbury; at Orangedale with Marble Mountain and Baddock and at Sydney with North Sydney, Synod Mines, Glace Bay and Lewisburg. Over 100,000 pounds of copper wire and between 13,000 and 14,000 cedar poles were used in the construction. The cost of building the line was nearly $100,000 and a rate has been struck at $1.25 for a three-minute conversation between 8 a. m. and 6 p. m., and 65c. for the same time between 6 p. m. and 8 a. m.

ZAMORA, MEX.—A telephone line is being built between this place and Chavinda.

OPICHEN, MEX.—A new telephone line is being constructed between this place and the town of Colentur, in this State (Yucatan).

CULIACAN, MEX.—A company is being organized here for the purpose of installing a new telephone exchange and to build and operate long distance lines throughout the State. Governor Francisco Canedo can give information.

CULIACAN, MEX.—A report has been made by the state Government of Sinaloa showing that there are 1058 miles of telephone lines in operation in the State. A new telephone lines has been constructed between the port of Topolobampo and the town of El Fuerte, along the Kansas City, Mexico and Orient Railroad.

Electric Light and Power.

SYLACAUGA, ALA.—The citizens have voted to issue $20,000 electric light and water bonds.

WYLAM, ALA.—There is some talk of constructing an electric light plant and water works here.

FLAGSTAFF, ARIZ.—The Flagstaff Electric Light Company contemplates installing a 60 or 75-kw generator with engine to correspond.

SEBASTOPOL, CAL.—G. W. Swain has secured a franchise for an electric light plant.

SAN FRANCISCO, CAL.—The Mutual Electric Light Co. has called a meeting of its stockholders for June 21 to vote an issue of $400,000 bonds, $250,000 to be sold for improvements and the remaining $150,000 to be held in treasury until such time as needed.

DENVER, COL.—The Colorado Power & Irrigation Company has secured a location on Grand River and has done some work on the intake and dam site. The company proposes to install two plants, the main plant having a capacity of 15,000-hp and a small auxiliary plant of 5000-hp. No contracts have yet been made for the machinery. Electric energy will be transmitted about 100 miles for mining, lighting, metallurgical processes and irrigating. It will be one year yet before the necessary stone and other construction work at the plant is completed.

WATERBURY, CONN.—The New Milford Power Company, which transmits electric power from its plant at Bulls Bridge on the Housatonic River to Waterbury for consumption by the Connecticut Railway & Lighting Company in this section has had to change all the glass insulators on the double line of aluminum wires and substitute porcelain insulators. Much more satisfactory results are now obtained. The transmission line is being extended to the Cheshire and New Britain districts, where the Connecticut Railway & Lighting Company is erecting distributing stations.

WASHINGTON, D. C.—Bids are wanted May 28 for furnishing and delivering at the Library of Congress incandescent electric lamps, hardware, plumbing and electrical supplies, etc. Address Bernard R. Green, superintendent.

TAMPA, FLA.—A special meeting of the stockholders of the Tampa Electric Company has been called May 30, 1904, to consider the advisability of an increase in the capital stock of the company by the amount of $100,000.

THOMASTON, GA.—The question of constructing water works and an electric light plant is under consideration. Ira E. Farmer is mayor.

POST FALLS, IDA.—The Washington Water Power Company, of Spokane, Wash., has decided to install a power plant here, and Clemens Herschel, of St. Paul, has been engaged to outline plans for developing power both from Spokane and Post Falls. The plant will have a capacity of 10,000 horse-power. The power will be used to operate the Coeur d'Alene electric railways and for the operation of numerous Coeur d'Alene mines.

ST. CHARLES, ILL.—Some improvements are planned for the municipal electric light plant in this city. They will include a 350-hp Corliss engine and one 160-kw generator. These improvements will be made during the summer.

NEW HAVEN, IND.—The town board has rejected all bids received for constructing an electric light plant here. Bids will be readvertised for at once. J. M. Jackson is town clerk.

PERU, IND.—It is proposed to construct a dam, electric power plant and an electric railway between Vincennes and West Baden. Jerome Herff, of Peru, can give further information.

MOORESVILLE, IND.—The Public Service Company is advertising for bids for the construction of the power-house for the water works and electric light plant. The plans and specifications are ready for distribution among applicants.

ELKHART, IND.—A mortgage for $1,750,000 has been filed by the St. Joseph & Elkhart Power Company, covering the immense power plant recently built on Hen Island, in the St. Joe River. The mortgage was filed for the benefit of the New York Securities and Trust Company, and is to take up an old mortgage and to secure enough money to carry out important and extensive improvements. The company has increased its capital stock from $50,000 to $250,000. Ernest A. Sanders is president.

BURLINGTON, IA.—The Merchants' Light & Power Company has been incorporated to construct an electric light plant. The capacity of the new plant at the outset will be 20,000 lights. The work of construction and installation of the plant will be under the supervision of Sweet & Caster, electrical and mechanical engineers, of Burlington.

NEW ORLEANS, LA.—It is stated that contracts are about to be let by the Consumers' Electric Company for its electric plant. It will cost complete about $1,000,000.

GLOUCESTER, MASS.—The Gloucester Electric Company intends to install a 500-kw. steam turbine.

SOUTH STILLWATER, MINN.—Bids are wanted May 28 for an electric light plant. J. J. Flather, Minneapolis, is the engineer, and B. L. Hanks the recorder.

CLARKSDALE, MISS.—A dynamo of 350 or 400-kw capacity, a boiler and a switchboard are to be installed in the municipal electric light plant in this place.

SALISBURY, MO.—A 100-kw alternator and one 200-hp boiler are to be installed in the municipal electric light plant in this place.

JOPLIN, MO.—A proposition will be voted upon June 6 next to appropriate $30,000 for the improvement of the municipal electric light plant in this city. If it carries, a 250-kw generator, engine and boiler will be installed.

LAMAR, MO.—The Lamar Light & Water Company will probably exchange all of its present machinery for larger units or install a duplicate of what apparatus it now has. The present plant is overloaded and there is a large demand for more lights.

VERSAILLES, MO.—Sealed proposals will be received at the office of the mayor until June 3 for furnishing material and equipment for a complete electric lighting plant in this city. Plans, specifications and instructions are on file at the office of A. G. Baker, secretary Board of Public Works, Versailles, Mo., and W. K. Palmer, Consulting Engineer, 402 Lyceum Building, Kansas City, Mo.

FREMONT, NEB.—The question of enlarging the electric light plant is under consideration.

RENO, NEV.—Reno is to have two water and power companies. Work on the opposition plant begins at once and will be completed before the summer is ended. Governor Sparks is the principal owner of the new enterprise and has announced that the people of Reno would have an opportunity to secure water or light from his company not later than next spring. The company owns water rights on Hunter Creek, five miles north of the city.

NIAGARA FALLS, N. Y.—The Niagara Falls Hydraulic Power & Mfg. Company contemplates building a new power house.

SAG HARBOR, L. I., N. Y.—Bonds to the amount of $24,000 have been sold, to be used for building and equipping an electric light plant.

SYRACUSE, N. Y.—Architect A. Russell, 321 Bastable Building, will soon have plans complete, ready for bids for a power plant for the new court house.

NEW YORK, N. Y.—The contract for the electrical apparatus for the New York Navy Yard, for which bids were opened April 23, has been awarded to the General Electric Co., of Schenectady, for $43,500.

SHELBY, N. C.—The electric light plant in this place is to be rebuilt and the system changed to three-phase. Messrs. A. W. McMurray and Hugh G. Miller are the owners.

BAINBRIDGE, OHIO.—A dynamo is to be installed at the electric light and water works.

BELLEFONTAINE, OHIO.—The entire rebuilding of the municipal electric light plant in this city is contemplated.

BELLAIRE, OHIO.—The Bellaire Light & Power Company will expend about $75,000 in improvements.

NAPOLEON, OHIO.—Bids are wanted June 7 for $25,000 electric light and water bonds. Address F. W. Hilgendorff, Village Clerk.

WILLIAMSBURG, OHIO.—Chas. Hoffman, City Clerk, writes that bids for constructing an electric light plant and town hall will be received about June 1.

ZANESVILLE, OHIO.—The city authorities are considering the advisability of installing electrical apparatus in their present water works pumping station and generating their own lighting current. At present the city pays $20,000 per year for lights.

EATON, OHIO.—The Eaton Public Service Co. has been incorporated, with a capital of $200,000. It is to absorb the electric light, power and ice companies and will establish an artificial gas plant and a heating system. H. J. Philips, C. S. Glass and J. R. Cook are among the incorporators.

LA GRANDE, ORE.—J. K. Romig, manager of the Sanger mills, has announced that during the spring his company will install a large power plant at that point.

PORTLAND, ORE.—The Washington Water Power Company is perfecting plans to increase the capacity of its plant fivefold, thus giving the city plants 70,000-hp. The estimated cost of the new work is estimated at $1,500,000.

MAHANOY CITY, PA.—The Economy Light, Heat & Power Company has applied for a charter to furnish electricity for light, heat and power in Mahanoy City, Mahanoy Township and Delano Township. Harrison Ball and John Matthias, of Mahanoy City; P. D. Jones, of Hazleton, and F. P. Spiese, of Tamaqua, are among the incorporators.

CLINTON, S. C.—The City Council is considering the proposition of Washington capitalists to construct an electric light plant and water works.

CHATTANOOGA, TENN.—An electric plant of 200 horse-power has been built to drive the $50,000 addition to the Sheland Machine Works at Chattanooga.

BURLINGTON, VT.—Plans are about to be prepared for the municipal electric light plant to cost about $58,000.

NORFOLK, VA.—R. B. Fentress has petitioned for a franchise for a light, heat and power plant.

OLYMPIA, WASH.—The Olympia Light & Power Company has secured a franchise from the city council for extensive alterations and extensions to its street car lines.

VANCOUVER BARRACKS, WASH.—Bids will be received until June 9 by F. G. Hodgson, Ch. Q. M., Vancouver Barracks, for constructing an electric lighting system at this post.

SEATTLE, WASH.—The Citizens' Light & Power Company has been granted a permit to extend its system in this city at an estimated cost of $50,000. The Seattle Lighting Company is also contemplating extensions of its system in different sections of the city.

RICHWOOD, W. VA.—The Richwood Light & Power Company proposes to purchase a 125-hp engine, one 150-hp boiler and a dynamo.

ANTIGO, WIS.—The station of the Antigo Electric Light & Power Company was destroyed by fire May 5. The loss is reported to have been $20,000.

SUN PRAIRIE, WIS.—The Sun Prairie Electric Lighting Company contemplates the construction of 12 miles of transmission line.

MITCHELL, ONT.—About $10,000 will be expended for improvements to the water works and electric light plant. Jas. Barnett is town clerk.

STAYNER, ONT.—Mr. Joseph Knox, owner of the electric light plant, intends to develop water power for electric lighting and power purposes. The transmission line will be 6 miles in length.

THE ELECTRIC RAILWAY.

JASPER, ALA.—The Jasper Water, Light & Power Company has been granted a franchise to operate an electric railway here. J. M. Crawford is manager of the company.

HARTFORD, CONN.—The contracts for the construction of 39 miles of the proposed electric line between Hartford and Worcester have been awarded. The general contract has been given to James F. Shaw & Company, of Boston; the contract for boilers and similar material to Thayer & Company, of Boston, and the contract for turbines to the General Electric Company. The engineers are Sheaf & Jaastad, of Boston. The present expectation is that the work of construction will be undertaken about July.

AKRON, IND.—The Wabash & Rochester Traction Company has decided to locate the power house in this city. The survey of the line and the work of constructing the power house are to begin soon.

INDIANAPOLIS, IND.—The Chicago & Northern Indiana Railroad Company has been incorporated here to build an electric line from this point to Chicago. Lester Soule, president of the Globe Construction Company, of Des Moines, is promoting the financial arrangements.

FORT WAYNE, IND.—It is said that there is a deal pending for the merger of the Fort Wayne Traction Company, the Fort Wayne & Southwestern Traction Company and the local electric light and power company, which also has the franchise for steam heating in Fort Wayne. The sale is being negotiated through John White. The new company is to construct a monster generating station, using the exhaust steam for heating the downtown districts. Eastern capital is helping to complete the deal.

WATERLOO, IA.—The officers of the Waterloo & Cedar Falls Rapid Transit Company have announced a change of name to the Waterloo, Cedar Falls & Northern Railway.

WASHINGTON, IA.—The Arnold Electric Power Station Company, of Chicago, has reported favorably on the construction of the Iowa City, Kalona & Washington Electric Railway. The report recommends 30 miles of single track and 3 miles of turnouts and switches, with one power house and three sub-stations.

WATERLOO, IA.—It is said that surveys are to be begun at once for the proposed electric railway from Des Moines to Waterloo. The principal promoters are Indiana men, but a local office has been opened here, in charge of W. W. Marsh, Thomas Cascaden, J. E. Sedgwick, Geo. E. Litchy and F. J. Fowler, of this city.

FRANKFORT, KY.—Articles of incorporation have been filed by the Columbia & Lebanon Interurban Railway Company, of Marion County, which has $1,000,000 capital stock. The company will build 46 miles of electric railway, from Lebanon to Columbia. The principal office of the company will be located at Lebanon. The incorporators are W. K. Azbil, of Columbia; R. W. Wathen, J. M. Knott and T. M. Estes, of Lebanon; L. C. Rawlings, of Bradfordsville, and W. W. Bradshaw and C. S. Harris, of Columbia.

SPRINGFIELD, MASS.—The street railway committee of the Legislature has gone over the route of the proposed electric railway from Lee to Westfield, and it is reported will make a favorable report on the project.

HUDSON, MASS.—The Hudson & Northboro Street Railway Company has been given a franchise for the construction of a line that, by connecting Hudson and Northboro, will furnish a short route between Hudson and Worcester.

NORTHBRIDGE, MASS.—The Selectmen of Northbridge have granted a franchise to the Uxbridge & Blackstone Street Railway Company to extend its line from its present terminus at Linwood to Plummer's, there to make connection with the Worcester & Blackstone Valley Street Railway.

ANN ARBOR, MICH.—A company is being organized for the purpose of building an electric railway from Ann Arbor to Lakeland, and possibly to Brighton. Detroit capitalists are interested and are investigating the question as to the right of way. It is proposed to utilize the old mill dam at Hamburg, long unused, for the purpose of securing the necessary power.

GRAND RAPIDS, MICH.—The West Michigan Interurban Railway Company has been incorporated under the laws of Michigan with a capital stock of $1,000,000, for the purpose of building an electric railway from Grand Rapids to Park, Oceana County, by way of Muskegon. F. A. Nims, of Muskegon, and J. K. Flood, of Hart, are among the incorporators. E. H. Christ, of Grand Rapids, is the chief engineer.

SPRINGFIELD, MO.—The Western Traction Company, of Indianapolis, has commenced a survey between Springfield and Carthage for its proposed line.

NEW YORK, N. Y.—The New York & Port Chester Railroad Company has filed with the County Clerk its plans for a 25-mile four-track electric railroad from 132d St. to the State line beyond Port Chester. It is to cost $16,000,000.

SCHENECTADY, N. Y.—The statement is made that the General Electric Company is to equip part of the Schenectady Railway Company's system for experimenting with the single-phase system.

NEW YORK, N. Y.—The Bronx Traction Company has been incorporated with a capital of $585,000. The company is formed as a result of the consolidation of five street surface railroad companies in Bronx Borough, known as the Suburban Traction Company; Van Nest, West Farms and Westchester Traction Co.; Wakefield & Westchester Traction Company; West Farms & Westchester Traction Company and the Williamsbridge and Westchester Traction Company. The directors of the new corporation are Edward A. Maher, of the Union Railway Company; Henry A. Robinson, of the Metropolitan Street Railway Company; Charles E. Warren, D. B. Hasbrouck, D. C. Moorehead, of Brooklyn; Frank S. Gannon, Oren Root, Jr., Reune Martin and M. G. Starrett, of New York City. Edward A. Maher is president of the Consolidated Company and Thomas W. Olcott, secretary and treasurer.

NEW YORK, N. Y.—As an offset to the proposition of the New York City Railway Company to give free transfers between its surface lines and the next rapid transit subway, if built by the Metropolitan, the Interborough Rapid Transit Company has formed a combination with the Schmidt & Gallatin moving platform syndicate to interchange transfers from the elevated or subway lines to a platform subway under Thirty-Fourth Street. According to the plan of the combination, the Thirty-Fourth Street crosstown connection from Ninth to Second Avenues, if made possible of construction, will be followed by like moving platform subways through Grand, Twenty-third, Fourteenth and Fifty-Ninth Streets, to connect the elevated and subway lines. The latter proposition covers the original route suggested by the moving platform people—over the Williamsburg Bridge, with a loop to the Battery—and then urges the second route across Thirty-fourth Street. This, it is argued, will afford relief to the congestion that will be caused when the Pennsylvania Railroad tunnel station is ready for use.

CHARLOTTE, N. C.—The construction of an electric car line from High Point, N. C., to Greensboro is likely to assume definite shape. A. L. Garrell, owner of several lines, is at the head of the movement.

COLUMBUS, OHIO.—Ralph Peters, superintendent of the Pennsylvania lines (steam) in this district, is quoted as saying that the Cincinnati & Muskingum Valley Railway is to be equipped with electricity between Trinway and Lancaster, in order to compete with electric lines that are building and contemplated.

TOLEDO, OHIO.—The Detroit, Monroe & Toledo Short Line has commenced giving regular service between Toledo and Detroit. The through trip can be made in three hours, and the fare is 90 cents. This completes the connection between the interurban roads of northern Ohio and Michigan, and makes possible a continuous trolley trip from Westfield, N. Y., to Port Huron, Mich.

DAYTON, OHIO.—The Inter-State Traction Company, which proposes to build a line from Dayton to Indianapolis by way of Camden and Connorsville, has elected these officers: D. M. Sanger, president; W. H. Heinz, first vice-president; E. R. Beard, second vice-president; C. A Cline, secretary; A. B. Landis, treasurer, and J. D. Boroff, general manager.

MEADVILLE, PA.—Charles W. Davis, of Linesville, one of the promoters of the proposed electric railway from this town to Geneva, Ohio, states that the contract for the building of the line will be let very soon.

GREENVILLE, PA.—A charter has been granted to the Greenville Street Railway Company, the incorporators being William C. Wilbert, Arthur H. Springer, R. H. Washabaugh, Samuel G. Bailey, J. D. Wild, Machael J. Ryan and M. A. Wilson, all of Pittsburg. The company will build an electric railway in Greenville.

PITTSBURG, PA.—The Jeannette, West Newton & Monongahela Railway Company has elected officers, and has arranged to begin construction before the end of the month. The capital is $4,000,000. All rights of way have been secured and the line will extend across country to the river district of Westmoreland County through a territory with a population of 20,000.

PHILADELPHIA, PA.—By the installation of additional equipment at its power plant at Second Street and Wyoming Avenue, the Philadelphia Rapid Transit Company is now enabled to supply power to all the lines south of Washington Avenue from the sub-station at Broad Street and Snyder Avenue. The difference of potential of transmission from the Wyoming plant is 13,500 volts, and the new installation is part of the company's general plan to high-voltage distribution.

NEALS SHOALS, S. C.—It is stated that W. J. Oliver has signed a contract to build an electric railway from Neals Shoals to Union. Work to begin June 1.

ANDERSON, S. C.—The Carolina Development Company, which is to have charge of the building of the electric railway between Anderson and Greenville, has organized as follows: F. G. Brown, J. A. Brock and R. S. Ligon, of Anderson; H. J. Haynsworth, of Greenville; Capt. E. A. Smyth, of Pelzer; Frank M. Faurier, S. S. Rhoads and Dr. Geo. E. Caughlin, of Indianapolis, and D. M. Stewart, of Xenia, Ohio, directors; Dr. Geo. E. Caughlin, president; R. S. Ligon, vice-president, and J. A. Brock, secretary and treasurer.

TEMPLE, TEX.—The Temple-Belton Traction Company, which is building an interurban electric railway between this place and Belton, has been formally organized with a capital stock of $250,000. Its principal office is at Temple. The incorporators are Calvin Green, W. C. Davies, J. C. Horn, A. C. Mayer, of Lewiston, Pa.; Samuel Watts, of Belleville, Pa.; L. F. Treaster, W. R. Barefoot, of Milsay, Pa.; H. E. Ahrens, of Reading, Pa.; A. M. Brown, of Tyrone, Pa.; A. F. Bentley, of Temple, and N. K. Smith, of Belton.

CHELAN, WASH.—Judge W. J. Long, of the Chelan Water Power Company, is promoting an electric railway from Rock Island through the wheat country around Big Bend and down the Columbia River to Chelan. A. Betts, of Spokane, and J. F. Sullivan, of Couer d'Alene, Idaho, are also interested in the project. The company is to be known as the Big Bend Railway Company.

TERREBONNE, QUE.—The Charlemagne Traction & Power Company is seeking incorporation to construct an electric railway connecting Terrebonne, Montcalm, L'Assomption and Berthier.

ST. THOMAS, ONT.—St. Thomas, which operates municipally the local street railway system, may take advantage of its charter to build an electric railway to Port Stanley. The City Council has referred the question to a special committee for consideration.

OTTAWA, ONT.—At the close of the last fiscal year of the Dominion, there were 759 miles of electric railway in Canada completed and in operation, 185 miles being double tracked. The paid up capital amounted to $57,274,853, of which the municipal aid amounted to $173,000. The gross earnings aggregated $7,233,677, an increase of $747,239, and the working expenses $4,472,858, an increase of $670,000, leaving the net earnings $2,760,819. The number of passengers carried was 155,662,812, an increase of nearly 18,000,000, and the freight carried amounted to 371,286 tons. Power was supplied in fifteen cases by water, and in thirty cases by steam. Ontario has 412 miles of electric railways, Quebec, 242; British Columbia, 49; Manitoba, 20; Nova Scotia, 24, and New Brunswick, 12.

New Industrial Companies.

THE PATRICK HIRSCH COMPANY, of New York, has been incorporated at Dover, Del., for the purpose of acquiring steam and electric railways. The capital stock is $10,000.

THE THOS. DEADERICK ELECTRIC COMPANY has been incorporated as the Standard Electric Company of Nashville, Tenn., capital $15,000. Thos. Deaderick, W. W. Page and others, of Nashville, are the incorporators.

Personal.

MR. CHARLES MANTNER, formerly manager for the H. Krantz Manufacturing Company, of Brooklyn, N. Y., is now manager of the Switchboard Manufacturing Co., New York.

MR. W. J. CLARK, manager of the foreign department of the General Electric Company, sailed for Europe May 24 on the North German Lloyd liner *Kaiser Wilhelm der Grosse.*

MR. H. W. RILEY, who superintended the construction of laying the electric lighting conduit in Havana on behalf of the contractors J. G. White & Company, New York, is back from Cuba, after completing the work.

MR. P. T. ACKERSON, formerly in charge of the supply sales department of the Western Electric Company at Chicago, has accepted the position as manager of sales for the American Transformer Company, of Newark, N. J.

PROF. ALBERT W. SMITH, head of the departments of mechanical and electrical engineering at Stanford University, Cal., has resigned in order to accept the post of director of Sibley College of Mechanical and Electrical Engineering at Cornell University.

MR. NORBERT B. KATES, of the expert commission house of Kates & Bok, New York, which concern handled considerable quantities of electrical equipment for the South American markets, is about to leave on an extended trip to Mexico with a view to closing some fair-sized orders for electrical equipment, supplies, etc.

MR. ARTHUR STANLEY RIGGS has returned from Manila, where for several years he was engaged in newspaper work, latterly as city editor of the *Cable Times.* The *Atlantic Monthly* several months ago printed an interesting paper from the pen of Mr. Riggs on the Philippine situation, which was widely noted in American papers.

MR. Y. KINOSITA, of Oki & Company, Yokohama and Tokio, contractors in electrical equipment to the Japanese Government, who has been on a hurried visit to this side, has left for home. It is confidently expected that shortly after his arrival in the Far East some very interesting contracts will be placed as a result of his trip here.

MR. CHUJI AWOYAMA, electrical engineer to the Imperial Japanese Department of Communication and to the Imperial Tokio Telephone Exchange, has sailed for home after a brief sojourn in the States. In a report which he will draw up for submission to the Japanese Government he will recommend the purchasing of a big quantity of electrical apparatus on this side.

PROF. CLARENCE FELDMANN, of the Darmstadt Technischen Hochschule, is on a visit of several months to the United States. Prof. Feldmann is well known to engineers as the designer of the Frankfort central stations the prototype of the great central stations of to-day, and from his writings, the most recent of which is a comprehensive treatise on the arc lamp.

MR. CYRUS ROBINSON, first vice-president and general manager of the Power and Mining Machinery Company, formerly the Loomis-Pettibone Gas Machinery Company and successor to the Holthoff Machinery Company, 52 William Street, New York, will leave for Mexico next week in order to attend the starting up of the Velardena Mining & Smelting Company's power plant, reference to which is made elsewhere in this issue.

MR. JAMES W. LYONS, who has been for many years associated with the Allis-Chalmers Co. in the capacity of engine salesman, has been appointed manager of the newly-created power department of the Allis-Chalmers Co., with headquarters in Chicago, the appointment taking effect Monday, May 16, 1904. This newly-created power department will control the sales of reciprocating steam engines, steam turbines (entire units including turbo-generators), condensers, gas engines, pumping engines, blowing engines, hoisting engines, air compressors. Mr. Lyons' promotion will gratify his many business friends throughout the country.

MR. B. G. WASSERMANN, of J. Wassermann Company, which concern is affiliated with the old established German commission house of J. Wassermann & Company, of Hamburg, and has recently opened offices at 35 South William Street, New York, leaves for South America early next month for the purpose of opening a branch establishment in Buenos Ayres, Argentine Republic, where yankee electrical equipment, supplies, etc., will be handled on an extensive scale for that market. Mr. Wassermann will be accompanied by Mr. Otto E. Glocke, formerly manager of the European department of the mercantile firm of G. Amsinck & Company. Mr. Glocke will have charge of the Buenos Ayres offices.

MR. G. MARCONI sailed back last Saturday to England again on the *Campania* to perfect his arrangements to furnish the Cunard Company with a daily news service. He arrived on the same vessel, and, not finding his contemplated trip to the Cape Breton station necessary, sailed on the steamer to put the finishing touches to his scheme. On his return trip he hopes to have everything in working order. The greater part of the voyage will be spent by Marconi in experimenting as to the most favorable situation on the vessel for the receiving and sending of messages. He says the rooms now in use are too small for the latest instruments, and he does not believe that they are in the best place—one amidships on the main deck and the other just aft of the bridge.

NEW INSTITUTE MEMBERS.—At the May meeting of the American Institute of Electrical Engineers, 64 new associate members were elected as follows: Adam, Fred B., secretary and manager, Frank Adam Electric Co., St. Louis, Mo.; Barclay, George, New Zealand Volunteers, Palmerston, Otago, N. Z.; Bates, Francis Reed, consulting engineer, Bogart-Bates Co., Seattle, Wash.; Beckett, Bergie Barry, student, Cornell University, Ithaca, N. Y.; Blizard, John Walter Frederick, chief draughtsman, Keystone Telephone Co., Philadelphia, Pa.; Bramhall, Charles A., manager, Diehl Mfg. Co., New York City; Brosius, James Simms, engineering apprentice, Westinghouse Electric Mfg. Co., Pittsburg, Pa.; Brown, Alfred Evelyn, partner, Scott and Brown, Christchurch, New Zealand; Byllesby, Henry Marison, president, H. M. Byllesby and Co., Chicago, Ill.; Curtis, Leonard E., vice-president and treasurer, Guanajuato Power and Electric Co., Colorado Springs, Colo.; Dean, George Cooper, member of firm Johnston and Dean, New York City; d'Humy, Fernand Emile, district electrician, Postal Telegraph Cable Co., Boston, Mass.; Dunwoody, Henry H. C., instructor, Commanding Signal Corps Post, Fort Myer, Va.; Edwards, Charles Griffin, assistant engineer, Electrical Commission of Baltimore, Md.; Eveleth, Charles Mirick, assistant engineer, American Telephone and Telegraph Co., New York City; Francisco, Ferris Le Roy, supervising electrician, Consolidated Tobacco Co., New York City; Fridenburg, Henry Leslie, secretary and manager, Electric Utilities Co., New York City; Fries, Jons Elias, engineering department, New York Edison Co.; Gale, Frank Harvey, advertising manager, General Electric Co., Schenectady, N. Y.; Gilliland, Clarence Rey, correspondent, Westinghouse Electric and Mfg. Co., Pittsburg, Pa.; Glenn, Charles Sewall, electrical inspector, Baltimore and Ohio R. R., Newark, Ohio; Goehst, J. Henry, construction superintendent, Chicago Edison Co.; Goldsmith, Leon, Westinghouse Electric and Mfg. Co., Columbus, Ohio; Hicks, De Forest, manager, Western Electric Co., Philadelphia, Pa.; Howell, Cecil Ashbrooke, transformer designing engineer, Wagner Electric Mfg. Co., St. Louis, Mo.; Howell, George D., engineer in charge, Lake Erie Traction Co., Philadelphia, Pa.; Hyman, Wallace Munroe, assistant P. R. Moses, New York City; Joseph, Theodore Harold, member of firm E. J. Electric Installation Co., New York City; Kodjbanoff, Basil George, illuminating engineer, Benjamin Electric Mfg. Co., New York City; Lamme, William Fenner, construction department Westinghouse Electric and Mfg. Co., San Francisco, Cal.; Lea, Edward S., sales manager DeLaval Steam Turbine Co., New York City; Lee, William S., Jr., vice-president and chief engineer, Catawba Power Co., Rock Hill, S. C.; Lombard, Percival Hall, salesman General Electric Co., San Francisco, Cal.; Ludwig, Rudolf Emmanuel, electrical engineer, Ludwig and Co., Atlanta, Ga.; Mansfield, Edward Stacey, Edison Electric Illuminating Co., Boston, Mass.; McKay, Maurice Parker, engineer, Westinghouse, Church, Kerr and Co., New York City; Moody, William Edgar, draughtsman, American Elevator Co., Columbus, Ohio; Moore, Clifford Thompson, electrician U. S. Navy Yard, League Island; Mountain, John Theodore, load despatcher, Chicago Edison Co.; Müller, Henry Nikola, electrician, Allegheny County Light Co., Pittsburg, Pa.; Nicholson, Lloyd Carlton, instructor, University of Missouri, Columbia, Mo.; Norton, William John, agent, Federal Electric Co., Baltimore, Md.; Nurian, Kerson, superintendent of construction, Main Switchboard, Mechanical and Electrical Dept., World's Fair, St. Louis, Mo.; Osthoff, Otto Earnest, electrical engineer, H. M. Byllesby and Co., Chicago, Ill.; Pettit, James Edward, chief operator, Postal Telegraph Cable Co., Chicago, Ill.; Pierson, Henry Gregory, member of firm, Foote, Pierson and Co., New York City; Potter, Herbert Sturgis, electrical engineer and contractor, Boston, Mass.; Roberts, George Clifford, electrical engineer, Philadelphia, Pa.; Schneider, Carl Albert, student, Columbia University, New York City; Schuler, L., electrical engineer, Wagner Electric Mfg. Co., St. Louis, Mo.; Schwabacher, Frank, student, Columbia University, New York City; Skog, Gustaf Emanuel, erecting engineer, Westinghouse Electric Mfg. Co., Wilkinsburg, Pa.; Slemin, Harry C., telephone engineer, Stromberg-Carlson Telephone Mfg. Co., Rochester, N. Y.; Smith, Robert James, superintendent, Canadian Electric and Water Power Co., Ltd., Perth, Ont., Can.; Stimpson, Clarence Arney, chief operator, Postal Telegraph Cable Co., Philadelphia, Pa.; Stratton, Samuel W., director of National Bureau of Standards, Washington, D. C.; Streng, Lewis Starr, assistant engineer, Public Service Corporation of New Jersey, Newark, N. J.; Thomas, Stephen A., chief electrical inspector, Department of Education, New York City; Wallace, John Eugene, assistant engineer, L. B. Stillwell, New York City; Weber, Frederick Carl, tester, General Electric Co., Schenectady, N. Y.; Wiswell, Orzo N., Snoqualmie Falls and White River Power Co., Snoqualmie Falls, Wash.; Wolls, William A., chief engineer Peruna Drug Mfg. Co., Columbus, Ohio; Woodmansee, Fay, electrical engineer, Sargent and Lundy, Chicago, Ill.; Youngblood, Frank James, special apprentice, British Westinghouse Electric and Mfg. Co., Manchester, England.

Legal.

BIG COLORADO JUDGMENT.—Judgment for $205,280.65 has been rendered in the district court at Colorado Springs, Col., against the Colorado Electric Company in favor of Eastern bondholders represented by the Union Trust Company, of Pittsburg, Pa. The court has ordered a public sale of the plant at Canon City and all other holdings of the company unless payment is made within five days. The judgment was rendered on a mortgage for $250,000, part of which has been paid. No defense was entered, the case going by default.

TELEPHONE RIGHTS OF WAY.—The law as interpreted by the Pennsylvania courts, defining the rights of telephone and telegraph companies says that a telephone company has no rights on private property except those which are granted by the owners, which is, no doubt, old and good law. As to the highways in the country, they have a restricted right of eminent domain, subject to a reasonable compensation to the abutting property owners, but no compensation can be demanded by abutting property owners in cities where wires are strung on streets with the permission of Councils. In no case has a telephone company the right to make use of house-tops for any purpose without the consent of the owner of the property, and the latter have redress for service and destruction of property where houses have been so used without permission.

MEASURING INSTRUMENT LITIGATION.—Judge Lacombe, of the United States Circuit Court for the Southern District of New York, on May 9, filed an opinion in the case of the Weston Electrical Instrument Company against the Whitney Electrical Instrument Company and Machado & Roller, declining to grant an injunction against the Whitney Company and Machado & Roller upon the Weston patent No. 392,387, which was recently sustained against the Jewell Electrical Instrument Company and the Keystone Electrical Instrument Company. The case was argued at length by Messrs. Kenyon & Kenyon on behalf of the Weston Company and by Mr. C. V. Edwards on behalf of the Whitney Company and submitted upon voluminous papers. Machado & Roller, the general selling agents of the Whitney Electrical Instrument Company, announce that, in addition to this recent emphatic decision another suit brought by the same Weston Company against the Whitney Electrical Instrument Company and themselves on Weston patent No. 446,489, likewise covering Weston instruments, was dismissed upon final hearing by the Court in October last and costs assessed on the Weston Company.

ANNUNCIATOR DROPS.—The U. S. Circuit Court of Appeals of the Sixth District has handed down an opinion sustaining the lower court in its decision declaring that the North Electric Co. had not infringed certain claims in a patent issued to James C. Warner and owned by the Western Electric Co., relating to an electric annunciator drop. The North Electric Co. was represented by Mr. Albert Lynn Lawrence, of Cleveland, and the appellants by Messrs. Rector, Barton and Tanner, of Chicago. One claim of the patent of Warner involved surrounding an annunciator coil with a soft iron shield to minimize induction therefrom as far as possible. The court held that it was not new to surround the magnet coil of an annunciator with a shield or tubing of soft iron, an English patent to Faulkner, issued in 1875, describing this construction. Prof. S. P. Thompson, in his "Elementary Treatise on Electricity in Magnetism," in the edition of 1887, also pointed out the use of a shield to secure the space outside of the coil from magnetic influence. A number of patents were adduced to show that the Warner claim for leading-in device of the wires of the helix through the armature is not new. The court held that if this claim is to be sustained at all, which is a doubtful matter, it can only be sustained by confining Warner to the specific device he has secured, and thus limited the defendant does not infringe. The court affirmed the decree dismissing the bill charging infringement.

Trade Notes.

BULLOCK ELECTRIC MFG. COMPANY announces that its New York offices, of which Mr. E. W. Goldschmidt is the district manager, have been moved to the Empire Building, 71 Broadway.

INCREASE OF SUMTER CAPITAL.—The capital stock of the Sumter Telephone Manufacturing Company, Sumter, S. C., is to be doubled. A new building has been added and new machinery installed, costing nearly $50,000, which has been paid out of the surplus profits.

D. M. STEWART MFG. COMPANY, of Chattanooga, Tenn., finds that Lavite is selling quite largely. It has made recent additions and improvements of its plant which will enable it to fill orders promptly. Lavite insulation is very well known throughout the electrical field.

FUSELESS ROSETTE.—Pass & Seymour, Inc., Solvay, N. Y., report that they are meeting with unqualified success in introducing their new fuseless rosette for concealed work. It is not only easy to install, but makes a finished job, completely concealing wires, tubes, etc. A request addressed to Pass & Seymour, Inc., mentioning their trade number 604, will bring a free sample.

CROCKER-WHEELER COMPANY, Ampere, N. J., has just issued a very tasteful pamphlet entitled "Uncle Sam Printer," giving an illustrated account of its fine installation of generators and hundreds of motors in the Government Printing Office at Washington, D. C. The pamphlet is based upon the series of articles on the subject that appeared in the ELECTRICAL WORLD & ENGINEER at the beginning of the year.

GERMANIA LAMPS.—The Germania Electric Lamp Company, Harrison, N. J., has just issued a very neatly gotten-up price list of its electric lamps. It contains some common sense facts about incandescent lamps, and half-tone illustrations of representative types of Germania lamps. The standard Germania lamps are made in efficiencies of 3.1 watts, 3.6 watts or 4 watts per candle, for voltages of from 75 to 130. The company also makes a complete line of special lamps.

THE INTERNATIONAL TELEPHONE MFG. COMPANY, Chicago, states that it was not affected adversely, either directly or indirectly, by the recent self-restoring drop patent decision. On the other hand it has had a constantly increasing demand for its new "never failing" self-restoring drop for new exchanges as well as for increasing boards of other makes. Its drop and jack can be fitted for any size plug and for mounting on any style of board.

UNDERWRITERS' RULES.—We have received from the Pettingell-Andrews Company, Boston, Mass., a copy of the National Electrical Code for the installation of electric wiring and apparatus, as recommended by the Underwriters' National Electric Association. It is of pocket size, and has a substantial green-leather cover into which it can be slipped and withdrawn. In this form it will be found very serviceable and ready for reference, as it can be easily carried in the pocket.

FLOATING CURRENT MOTOR.—Mr. J. Rauscher, electric push button manufacturer, at St. Paul, Minn., has invented and received a patent for a floating current motor. Mr. Rauscher's factory being located for 12 years on West Third Street, giving him a good view of the Mississippi River, caused him to think of the enormous power being wasted. During his leisure hours he made a few sketches and then a model. The first not being satisfactory he made a second and then a third which he took and tested in the Mississippi River, and which test proved highly satisfactory. He is now building a more highly improved motor, all improvements being covered by patents applied for, which he will give a thorough test on the Mississippi River about July 1. It is claimed that this machine can be built to produce 500-hp.

SPECIAL LIGHTING AT HARTFORD, CONN.—For the encampment and reunion last month at Hartford, Conn., of the Army of the Potomac, some fine special lighting effects were carried out. Nearly 25,000 lights in all were used temporarily on 1½ miles of street, the extra work requiring 15 men 10 days, and then it could not have been done without the aid of the Norbitt sockett. The current was furnished chiefly from the storage battery of the Hartford Electric Light Company. General Electric lamps were used. The construction was superintended by Mr. E. Baldwin, of Rice & Baldwin, local electrical contractors, who carried out all the plans and designs most successfully. All the emblems, stars, etc., were of the new changeable system of the Electric Carriage Call Company, of which Mr. Mortimer Norden is general manager. The local press spoke highly of the whole work.

CURTIS STEAM TURBINE.—The Curtis steam turbine has been very fully described and illustrated in these columns, and our readers are already familiar with this recent type of prime mover and its advantages. It is now classed as a standard product and is the subject of a special trade pamphlet just issued by the General Electric Company. The pamphlet is gotten up in the finished and artistic style which characterizes this company's trade literature. It is printed on fine coated paper, with artistically executed engravings. The machine is very completely and clearly described and the many excellent half-tones and line illustrations show it off to the best advantage. Many illustrations of details are also shown for the first time. The list of illustrations includes turbines of various capacities, ranging from 500-kw to 5000-kw, a particularly interesting feature being those showing the comparative sizes of turbines and steam engines of equivalent capacities. As is well known, the steam engine suffers by comparison. The rapidity with which these turbines have grown in favor forms a unique chapter in the history of industrial development, and engineers will no doubt peruse the pages of this new catalogue with unusual interest and care.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED MAY 17, 1904.

[Conducted by Rosenbaum & Stockbridge, Patent Att'ys, 140 Nassau St., N. Y.]

759,858. AIR BRAKE MECHANISM; Guss A. Brooks, Covington, Ky. App. filed June 15, 1903. When the car motor is driven by the momentum of the car, it serves as a generator to supply current to an electric motor which actuates an air compressor for the brakes.

759,880. ELECTRIC ARC LAMP; Otto Gross, Manchester, England. App. filed Dec. 11, 1903. Details of a clock-work driving friction wheels which bear directly upon the carbon rod to feed the same.

759,887. PROCESS OF MANUFACTURING PEROXIDS; Friedrich Hinz, Berlin, Germany. App. filed Nov. 23, 1903. (See page 1026.)

759,900. ARMATURE WINDING; Frank A. Merrick, Johnstown, Pa. App. filed Oct. 25, 1900. The end connections of each coil are made with two bends, of offsets, in substantially radial directions, so that each end portion has two parts which lie entirely in different circumferential planes.

759,904. REGULATING APPARATUS FOR THEATRICAL ELECTRIC LIGHTING; Ernst F. Moy and Percy H. Bastie, St. Pancras, London, England. App. filed Dec. 11, 1903. Regulating apparatus enabling the operator to control the dimmers separately or collectively from a distance.

759,909. ELECTRICAL FURNACE; Richard M. Pelton, Detroit, Mich. App. filed Dec. 3, 1902. (See page 1026.)

759,915. ELECTRIC SWITCH; Max Von Recklinghausen, New York, N. Y. App. filed April 22, 1902. Details of a cut-out wherein the circuit is broken by a sudden movement while the contacts are immersed in oil, the device being especially adapted for making a quick rupture of the starting circuit of vapor electric lamps.

759,916. QUICK BREAK OIL SWITCH; Max Von Recklinghausen, New York, N. Y. App. filed April 22, 1902. A modification of the preceding invention.

759,927. COIL CASING; Charles F. Splitdorf, New York, N. Y. App. filed July 24, 1903. Details of a water and dust proof casing for induction coils; also an inclined passage for the wires leading to the binding posts, for shedding rain water.

759,941. PLUG RECEPTACLE FOR ELECTRIC CIRCUITS; John H. Trumbull, Plainville, Conn. App. filed Oct. 9, 1903. Details of a receptacle set flush in the wall and having a cover plate which ordinarily closes the orifice when the lamp is not in position.

759,962. PLURAL LAMP SOCKET; Reuben B. Benjamin, Chicago, Ill. App. filed Dec. 9, 1901. Details of construction of a cluster socket including the arrangement of the various contacts beneath the finishing cap and their mounting upon the insulating base.

759,963. PLURAL LAMP SOCKET; Reuben B. Benjamin, Chicago, Ill. App. filed July 18, 1902. Further details of a cluster socket having special reference to a series connection of the lamp.

759,967. ALTERNATING CURRENT MOTOR; Alexander J. Churchward, Brooklyn, N. Y. App. filed March 29, 1897. Means for keeping the armature at synchronous speed in a machine of the ordinary direct current type, when supplied by alternating currents.

759,981. ELECTRIC CABLE; Johannes Frisch, Mulheim-on-the-Rhine, Germany. App. filed May 5, 1902. The cable has a core of insulating material of star-shaped cross-section, the conducting wires being wound spirally about the same, the object being to lessen the electro-static capacity.

759,987. FACSIMILE TELEGRAPH APPARATUS; Ernst K. Gruhn, Dresden, Germany. App. filed Nov. 20, 1902. A stylus, a lever connected therewith and mounted to have a bodily as well as an oscillatory movement, a resistance body whose resistance is varied by the oscillatory movements of the lever, whereby the movement of the stylus is decomposed into orthogonal co-ordinates to effect a variation in the resistance of the line conductors.

760,029. TELEGRAPH SOUNDER; John F. Skirrow, East Orange, N. J. App. filed Jan. 8, 1904. A sounder wherein the electro-magnet may be adjusted toward and from the armature without changing the angular relation of the magnet cores and the armature.

760,057. PROCESS OF ELECTRICALLY SMELTING MATERIALS; Alfred H. Cowles, Cleveland, Ohio. App. filed Oct. 20, 1903. The material is placed in a conductive receptacle, the walls of which are kept cool by circulation of water to prevent short-circuiting of the current through them which would otherwise occur by reason of the heated condition of the material in contact with the walls.

760,065. BASE FOR INCANDESCENT LAMPS; Howard Gilmore, Boston, Mass. App. filed Nov. 22, 1901. The porcelain button in the end of the base is held in place by a shell eyeletted in.

760,075. ELECTRIC HEATER; George I. Leonard, Pasadena, Cal. App. filed Oct. 27, 1902. The resistance is a sheet of asbestos coated with a film of rubber over which a layer of graphite is placed.

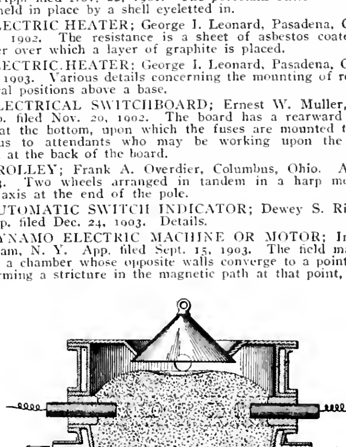
760,076. ELECTRIC HEATER; George I. Leonard, Pasadena, Cal. App. filed Jan. 22, 1903. Various details concerning the mounting of resistance plates in vertical positions above a base.

760,077. ELECTRICAL SWITCHBOARD; Ernest W. Muller, Brooklyn, N. Y. App. filed Nov. 20, 1902. The board has a rearward horizontal extension at the bottom, upon which the fuses are mounted to make it less dangerous to attendants who may be working upon the other devices mounted at the back of the board.

760,079. TROLLEY; Frank A. Overdier, Columbus, Ohio. App. filed June 30, 1903. Two wheels arranged in tandem in a harp mounted upon a vertical axis at the end of the pole.

760,081. AUTOMATIC SWITCH INDICATOR; Dewey S. Rice, Weatherly, Pa. App. filed Dec. 24, 1903. Details.

760,086. DYNAMO ELECTRIC MACHINE OR MOTOR; Imle E. Storey, Amsterdam, N. Y. App. filed Sept. 15, 1903. The field magnet core and pole has a chamber whose opposite walls converge to a point near the pole face, forming a stricture in the magnetic path at that point, to prevent the



760,057.—Process of Electrically Smelting Materials.

lines of force from serging from one-half of the pole into the other by reason of the rotary motion of the armature.

760,091. AUTOMATIC REGULATOR FOR ELECTRIC CIRCUITS; Montgomery Waddell, New York, N. Y. App. filed June 18, 1903. A shunt wound generator, a variable resistance in series with its field magnet winding, electro-magnetic means for controlling the resistance, said means being in series with the working circuit of the generator and also having a coil connected on one side to the working circuit and on the other side to the field magnet winding between the same and the resistance.

760,096. PROTECTING DEVICE FOR VAPOR ELECTRIC APPARATUS; James R. Baker, Arlington, N. J. App. filed Nov. 6, 1903. The pockets for the mercury electrodes contain a cushioning material, preventing the shock which occurs when the mercury forcibly flows into the pocket, from rupturing the lamp.

760,119. MEANS FOR PROTECTING VAPOR ELECTRIC APPARATUS; Peter Cooper Hewitt, New York, N. Y. App. filed Dec. 22, 1903. A modification of the preceding invention.

760,132. CIRCUIT CLOSER; James W. Leech, Staunton, Va. App. filed Oct. 10, 1903. Details.

760,143. APPARATUS FOR AMPLIFYING OR REINFORCING TELEPHONE CURRENTS; Joseph J. O'Connell, Chicago, Ill. App. filed Aug. 22, 1903. (See page 1028.)

760,145. GUARD FOR TROLLEY WHEELS; Charles O. Phillips, Kalamazoo, Mich. App. filed March 2, 1904. Details.

760,159. ELECTRIC BLOCK SIGNAL SYSTEM; Tony Silvene, Victoria, Can. App. filed May 20, 1902. Details.

760,163. TROLLEY CATCHER; Irwin W. Smyth, Dayton, Ohio. App. filed Jan. 25, 1904. A spring drum and pawl and ratchet arrangement for winding up the cord.

760,184. TROLLEY POLE HEAD; Robert I. E. Dunn, Dallas, Tex. App. filed Aug. 29, 1903. Details.

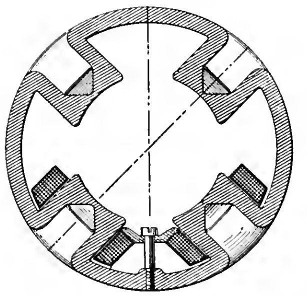
760,209. CIRCUIT CONTROLLER; Paul H. Jaehnig, Newark, N. J. App. filed March 1, 1904. Details of construction of an automatic switch for electric signs.

760,223. ELECTRIC RAILWAY; Thomas D. Lovell, Beverly, Mass. App. filed Jan. 22, 1904. A block system in which the movement of the cars on a single pack road, automatically cuts off the current from adjacent blocks.

760,231. TROLLEY BASE; Peter D. Milloy, Buffalo, N. Y. App. filed Nov. 16, 1903. The object is to produce a low base in which the revolving section surrounds and incloses a greater portion of the fixed section and revolves upon horizontal bearings which are not exposed to the elements.

760,234. ELECTRICAL CAB SIGNAL; Edward McClintock, Merriam Park, Minn. App. filed Sept. 5, 1903. Details of a signal intended to show when the train runs past a danger signal.

760,280. ELECTRIC WATER HEATER; Richard Toennes, Boonville, Mo.



760,086.—Dynamo Electric Machine or Motor.

App. filed Jan. 27, 1904. The water is caused to flow through devious passages, the walls of which form the sides of the circuits.

760,281. ELECTRIC ALARM; Herbert Trull, Fernie, Canada. App. filed Sept. 17, 1903. A fire alarm comprising a tube containing a liquid, the expansion of which moves a plunger to close a circuit.

760,289. ELECTRICAL APPARATUS FOR WORKING RECIPROCATING TOOLS; Alfred D. Williamson and Cecil L. Sumpter, Sheffield, Eng. App. filed Jan. 31, 1903. Apparatus for working planing machines and the like in which provision is made for automatically reversing the direction of the tool and making the return stroke more rapid than the operating stroke.

760,302. PURIFYING APPARATUS; Pierre J. Boucher, Cleveland, Ohio. App. filed March 28, 1903. (See page 1026.)

760,305. COUPLING FOR ELECTRIC WIRES; Ricardo G. Castillo, Mexico, Mex. App. filed Sept. 9, 1903. The coupling comprises a block of insulating material carrying a coupling wire, the conductor wires attached to the block and terminating thereat, are fitted with mercury cups into which the ends of the coupling wire dip to establish a good through connection.

760,312. PROCESS OF MAKING CALCIUM CARBID; Alfred H. Cowles, Cleveland, Ohio. App. filed June 28, 1902. (See page 1026.)

760,315. COMBINED ELECTRIC HEATER AND BATTERY; Jesse R. Davis, Parkersburg, W. Va. App. filed Dec. 8, 1903. Details.

760,325. ELECTRIC RAILWAY; William R. Fearn, Camden, N. J. App. filed Dec. 16, 1903. Details.

760,326. UNIVERSAL FLOOR BOX FOR THE DISTRIBUTION OF ELECTRIC WIRES; John Fountain, Jr., Elizabeth, N. J. App. filed Dec. 16, 1902. The cover of the box is interchangeable and constructed to receive either a supplemental cap flush with the cover, or a nozzle projecting above the cover, both of which have a water-tight connection with the box.

760,330. TROLLEY POLE; James Furgason, Montour Falls, N. Y. App. filed May 28, 1903. Details.

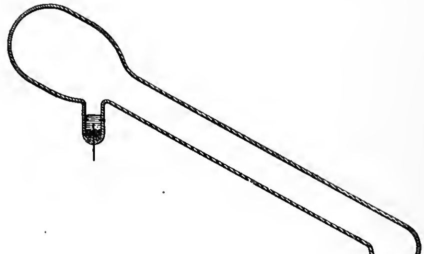
760,361. STEADYING RESISTANCE FOR ARC LAMPS; Louis Wolff, Berlin, Germany. App. filed Dec. 16, 1903. The lamp resistance is coiled around a fireproof layer of insulating material on the outside of the solenoid.

760,375. ELECTRIC LAMP CLUSTER; Reuben B. Benjamin, Chicago, Ill. App. filed March 3, 1902. Details.

760,376. ELECTRIC LAMP CLUSTER; Reuben B. Benjamin, Chicago, Ill. App. filed Nov. 12, 1902. Details.

760,387. ELECTRIC SWITCH; Egbert R. Dull, Chicago, Ill. App. filed Aug. 5, 1901. Details of construction of a switch for operating electric signs.

760,399. SELECTIVE SIGNAL SYSTEM; Fred C. Penfield and Olin Templin, Lawrence, Kan. App. filed March 17, 1902. An improvement upon a pre-



760,119.—Means for Protecting Vapor Electric Apparatus.

vious invention of the same parties, whereby the system is adapted for the common battery method of operating telephone circuits.

760,400. AUTOMATIC OIL SWITCH; Max Von Recklinghausen, New York, N. Y. App. filed Jan. 6, 1904. The invention resides in the construction of a liquid-tight casing for the switch, the latter being operated by a solenoid.

760,408. DYNAMO ELECTRIC MACHINE; Leonard Wilson, Pittsfield, Mass. App. filed June 1, 1903. A construction whereby a wide brush may be used on high speed machines, thus obtaining low current densities and providing ample time for proper reversal and yet wholly avoiding local excess or uneven distribution of current.

Twenty-Seventh Convention of the National Electric Light Association.

THE twenty-seventh convention of the National Electric Light Association was called to order by President C. L. Edgar at the Hotel Vendome, Boston, Mass., at 10.30 A.M., May 24, some 400 delegates being then in attendance in the hall. Secretary E. H. Davis read a number of letters from prominent men as to absence or intention to be present.

PRESIDENT'S ADDRESS.

President Edgar then delivered an able address which was listened to most intently by one of the largest gatherings that ever witnessed the opening exercises of a convention. He referred to the fact that he had been one of the attendants at the former convention in 1887, as the guest of Capt. Brophy, when he visited the old Thomson-Houston works at Lynn, Mass., when the entire number of men employed was not equal to the number now in any one of a dozen departments. At that time the Boston Edison Company was the possessor of one small station, with a total load connected to its overhead system equal to the fortnightly growth of the present year. Referring to the general growth of the central station business, as represented by the members of the Association distributed throughout the United States and Canada, he found that the number of electric light stations has increased during these seventeen years more than nine fold. Naturally the membership of the Association has not grown in proportion, but the fact that there are now upon the rolls 583 members, as compared with only 158 at that time, is a matter for sincere congratulations. "The work done by my two immediate predecessors in getting new members into the Association stands by itself. The growth this year, as the result of their work, has been rather slow. At the same time, the Association has had a healthy and steady increase in membership and I feel satisfied that it will continue in at least as great a ratio as during the past year."

Mr. Edgar then rehearsed the facts with regard to the Union Engineering Building, New York City, the gift of Mr. Carnegie, and announced that the Association would be able to place its offices there, a plan which he heartily recommended, for its many and obvious advantages. He then took up the question of the constitution and said: "The time has come when it seems desirable to make a somewhat desirable change in the by-laws of your Association. When it was organized some nineteen years ago the industry consisted of a large number of small companies, located throughout the country. Almost without exception, these companies were confined each to its own city; in fact, there were a number of cities, especially those of the larger size, that had a number of competing companies. As time went on, consolidations took place, either by the purchase of a local company by a syndicate or holding company or by the actual amalgamation either of competing or of adjoining companies. This has, at the present time, been carried on to such an extent that in some sections of the country all of the small companies have now been obliterated and one large corporation now covers the territory and does the entire work. A most striking example of this kind comes under my own personal observation. The Boston Edison Company has taken the place of fifteen local lighting companies, all of whom were eligible for membership in our Association. Under the regulations of this State it is necessary to actually wind up these local companies, not only in business, but in a corporate sense, and a number of them have, therefore, had to resign from the Association. Within the next year or two there will be only one company left and the actual membership in the Association will be cut down from seven to one. This is going on all over the country and is a matter of serious concern for the future of the Association. The matter has been discussed at considerable length by the Executive Committee and numerous suggestions have been made for overcoming the difficulty. These have been put in concrete form by your secretary and will be submitted to the Association in executive session. Speaking generally, the remedy suggested is to have another class of membership, consisting of individuals called junior active members, to be elected under some sort of supervision of the active member with whom they are connected in business and paying as dues an amount in keeping with their privileges. I trust that this matter will be given serious consideration by the members of the Association within the next two or three days, so that a conclusion can be arrived at the executive session on Thursday."

Mr. Edgar then discussed a number of important Association topics. The electric lighting industry in this country, he said, has in the past, in certain definite directions, been under somewhat serious disadvantages because of a lack of a comprehensive and correct directory of the industry. In most other lines of work it has been possible for manufacturers, investors or inquirers generally to find out something about the industry in which they were interested. This want was brought especially to his attention sometime during the early part of the year. One of the various circulars issued periodically by the assistant secretary was sent out over the President's name and mailed from Boston. The number of letters returned undelivered was astonishing and the conclusion was arrived at that all the existing lists were worse than useless. About this time a prospect appeared of this work being taken up by one of the members of the Association and put on a par with the publications of other industries of like character. President Edgar thought that members should give their earnest support to this enterprise, incidentally because it is carried on by one of the members, but primarily and selfishly because all members are interested in having it a success.

Referring to the International Electrical Congress, he announced that the Association had accepted an invitation from the Congress inviting it to contribute three papers and to send the authors as delegates to the Congress. The work of the Congress is truly international in its character, papers having been promised by some of the most noted scientists in the world, both in this country and abroad, and for this reason it is extremely desirable that the Association's representation at the Congress shall be in keeping with its standing. Mr. Edgar said that until he became president of the Association, he had no suspicion of the vast amount of work carried on at the permanent office in New York. Under the efficient direction of the assistant secretary, a large and varied correspondence is kept up with the member companies, an average of over ten letters daily being written on all sorts of subjects. In addition to this, various compilations have been made during the year and most of these have been forwarded to the members from time to time. The office is now engaged upon various other reports, notices of which will be given at the proper time. In short, the Association has a thorough and business-like organization, capable of taking up and intelligently discussing almost any subject of interest to the members of the Association.

"Sometime during the winter it was suggested by one of the members of the Executive Committee that there must be a vast amount of valuable information in the records of the Association which were practically useless because of the lack of an index. The matter was taken up at once and there has been prepared a complete index of the papers and reports presented to this Association since its organization, indexed and cross-indexed in various ways. It is intended to publish this as a separate volume for distribution with the proceedings of this convention. I think that none who have not specially looked into this subject realize the great amount of information locked up in the proceedings of the conventions, but which will be available at a moment's notice when this index is published."

Mr. Edgar then noted the resignation of Mr. C. O. Baker, Jr., as master of transportation, commending his long and efficient service; and stated that he had appointed Mr. G. F. Porter in his stead. He then referred to items of the programme and suggested the merging of the "Question Box" and "Wrinkles" departments. He also alluded appropriately to the questions of central station advertising and the sudden and large business that developed last winter in electric thawing—a subject calling, he thought, for special report. He enlarged also upon the duties of the Executive Committee, which was a body intended to do some work, for even at the best the position of president of the Association was a hard one. "I think that the Executive Committee should be chosen with some reference to their geographical location and with considerable reference to the size of the companies that they represent. Then, in order to make it easy and possible for them to attend the periodical meetings of the committee, an arrangement should be authorized for meeting the necessary expense of these meetings. This matter has been discussed by the Executive Committee during the past year, and I hope they will have some definite suggestions to offer in a report that they will make at the executive session on Thursday.

"Even if this can be accomplished, I realize that the difficulty is fundamental. We must look to our permanent officers to keep the work of the Association going in the right direction. It devolves upon them to instruct the incoming administration as to the precedents and policy of the past and in general to keep the permanent policy of the organization before the mind of each new executive, leaving the latter the privilege of bringing to the office and to the work the strength of his own personality and thus, by a mixture of the old and the new, build up an organization that shall stand distinct and unique among its compeers."

Mr. E. B. Weeks, of Kansas City, one of the earliest presidents of the Association, having been called upon by President Edgar for some remarks, spoke of the enormous growth of the electrical industries, which within the compass of one generation has arrived at the point where the investment runs into billions. He referred to the fact that the great pioneers like Edison, Thomson, Weston, Brush and Sprague, who, with their contemporaries and followers, laid the foundations of electrical industry of to-day, are still actively engaged in enterprises of great moment. The Association is unique in that under it the scientific or technical and the commercial elements have worked together. Contributing to its proceedings have been men like the late Prof. Rowland, men who with little attention to commercial considerations, devoted their lives to study and experimental research; and men of affairs like Mr. Marsden Perry, of Providence, who put hundreds of millions into applied electricity.

PROGRESS.

The report of the Committee on Progress, Mr. T. C. Martin, was a pamphlet of some 36 pages, dealing with a variety of topics of interest to central station managers. The figures and growth of the industry were shown, and the power plants of the lighting and railway systems of the country were contrasted. It was shown that in 1902 the dynamo capacity of the street railways was 1,204,238 hp, and that of the lighting plants was 1,615,480 hp. The output as reported by the companies showed the capacity of the railways to be in use about 8 hours daily and that of the lighting systems 6 hours. Comparisons were also made between the United States and Great Britain, Germany and Spain. The German and English plants average larger than ours. It was shown that 5 watts of new apparatus was installed per head of population in Spain in 1903, in Germany 7.5 watts in 1902; 12 watts per head in England in 1902-3, and 16 watts in the United States of America in 1902. Madrid has 66 watts installed per inhabitant, as compared with 48 watts in Berlin. The profits of the Spanish stations run high, reaching frequently 30 to 35 per cent. Details were then given as to London and Paris, the price per arc in the latter city reaching $240. Figures were cited as to American rates for current.

Mr. Martin then reviewed the progress in the lighting art, and gave a number of details as to the Nernst, Cooper Hewitt, magnetite arc, osmium, Blandel colored arcs, Just incandescent, reflector lamps and other lamps now competing for a foothold. Reference with data was also made to the twenty-fifth anniversary of the Edison incandescent lamp, and some comparisons were then made with gas. A large section of the report was next devoted to electric heating, citing the 20,000 electrically-heated cars in this country; the special plant in the Government Printing Office at Washington, the Berg hat factory in New Jersey and the cooking of waffles in large quantities for the students at Harvard. A final section was devoted to the development of the three-phase central station at Dublin, Ireland, during the present year.

In the discussion of Mr. Martin's paper Mr. E. F. McCabe, of Lewistown, Pa., referred to the fact that the Census statistics showed there is invested in electric lighting companies $504,000,000, giving a gross income of $85,000,000 and a net income of only $17,000,000. Mr. Martin said he had no reason whatever to question the accuracy of these figures, as they were based upon statements of central station men made to the Census Office at Washington. Mr. Samuel Scovill, of Cleveland, Ohio, said that part of the large capitalization should be considered to represent experience—the foresight, courage, ingenuity and inventiveness which have gone to create a great industry. Mr. Arthur Williams, in referring to the Nernst lamp, said he considered its great field to lie just between the largest size of incandescent lamp that can be used conveniently and the smallest size of arc lamp that will give satisfactory results. Here is a gap which the Nernst lamp of three and six glowers fills very satisfactorily and in which at the present time seems to have no entirely satisfactory competitor. The Nernst lamp in combination with the ordinary incandescent lamp, which latter is of a more yellow color, gives very satisfactory lighting results, and he referred to the satisfactory illumination in a club largely used in exhibiting pictures where the lighting was obtained from Nernst lamps at the ceiling and incandescent lamps at the cornices. A year ago it was reported that more than 400,000 Nernst lamps of various sizes were in use in England for interior and outdoor lighting, and very successfully for municipal lighting. He thinks the English experience is that the larger lamp has a greater field.

A THREE-WIRE, 250-500-VOLT LIGHTING SYSTEM.

Mr. Walter I. Barnes, in a paper of the above title, gave an account of the three-wire, 250-500-volt lighting system of the Narragansett Electric Lighting Company, Providence, R. I. The adoption of this system was decided upon in May, 1899, at which time the company had a connected load of about 4,900 kw in alternating current, 2,700 kw in direct-current, 500-volt motors, and 1,400 kw in arc lamps. The previous year an underground conduit system had been commenced and in December, 1901, 40 miles of streets had been opened and 1,700,000 ft. of ducts laid, in which were drawn about 2,000,000 ft. of cable, 1,100,000 ft. of which belonged to the new direct-current system. A storage battery was also installed consisting of 296 cells of 43 plates, the eight-hour discharge rate being 840 amp.

While the conduit system and storage battery were being installed, active preparations were being made whereby existing installations on the alternating-current, two-wire system might be readily transferred to the direct-current, three-wire system. The several sections of the city that were included in the change were served with about 50,000 incandescent lamps, 1,000 arc lamps and 2,000 hp of stationary motors, which installations were reconstructed to comply with the requirements of the new system. The commercial series arc lamps were replaced by multiple enclosed arc lamps, and the series generators thus released from service at the central station. All motors of the direct-current type were connected to the outside of 500-volt wires. When the changes have been finally accomplished the entire incandescent lamp business of the company, amounting to about 185,000 lamps on a 16-cp basis, will be operated at 250 volts and all motors, both direct-current and alternating-current, will be 500-volt machines. The 250-volt incandescent lamps average 3.3 watts per candle-power and have a useful candle-power area of not less than 4,000 hours, assuming the smashing point to be 80 per cent. of the initial candle-power. In 1899 the average watts for this type of lamp varied from 3.8 to 4. The arc lamps at present used are the twin-carbon enclosed type and operated multiple on 250-volt circuits, the current averaging 2.3 amp. and the energy of the lamp about 575 watts.

The discussion of the paper by Mr. Barnes was quite extensive, covering principally the subjects of grounded distribution and the twin arc lamp used on the Providence circuits. Mr. Junkersfeld expressed doubt if a 250-500-volt system has any advantage over the 125-250-volt system. In the incandescent lamp system there is a considerable difference in the energy loss, owing to the use of low-efficiency lamps, and the arc lamp situation is even more serious. The meter losses are double and the meter slip in the course of a year should amount to a very considerable item. While the difference in the investment required may offset these disadvantages, the adoption elsewhere of the system should be a matter to be very carefully considered. Even under circumstances where it might appear particularly adapted the straight alternating-current system would be a serious competitor. Mr. Alex. Dow thought that with the neutral earthed at different points there would, in towns where there is an electric railway system, be a considerable flow of railway current through the neutral circuit of the lighting system. In a case which came under his observation where two earths were on the neutral three-wire system about 8,000 ft. apart, there was a maintained difference of potential of 10 volts during the evening peak of the electric railway load, this resulting in serious disturbances of regulation and necessitating a special provision for balancing the three-wire system at different points. At times in such cases the current may be so large as to seriously heat the conductors.

Mr. Woodward said that in Providence the lead sheaths of all cables are bonded together in every manhole and there is in every manhole a ground plate bonded to the sheaths and to the copper neutral. In several years' operation no trouble was met with from railway current except in one section of the city very near to a point where the railway cables cross the river. Replying to Mr. Junkersfeld criticisms, he said he understood that by "slip" was meant unaccounted-for meter current, and he failed to see how there would be any more slip with 500-volt meters than with 250-volt meters. When it is considered that a single sub-station with a 250-500-volt, three-wire system would cover 16 times the area that could be supplied from a sub-station operating at 125-250 volts, it would seem a system using the higher voltage would be the better. As to alternating-current competition, he did not see how all classes of motors and all classes of lighting could be supplied with alternating currents at all times, he did not know of a single central station supplying a large area where variable-speed motors are used which has confined itself to alternating-current supply alone. Mr. H. L. Doherty, referring to the matter of meter slip, said that since the torque on the meter is proportional to the amperage and as current is supplied at a higher voltage, the slip would be doubled. As an example of what meter shunt losses may mean, he cited a neutral alternating-current circuit at Madison, Wis., where the shunt meter losses amount to more than the core losses of the transformers. Mr. P. G. Gossler, referring to an account in the paper of the wiring of the Union Trust Building in Providence, the frame of which is used as a neutral conductor, asked what the practice was in buildings not having metallic frames. In reply Mr. Woodward said that in these cases a copper neutral would be run.

In reply to a question from Mr. William Brophy, Mr. Woodward said that the ground of the system consists of a copper conductor neutral; the lead sheathing of the entire cable system and the grounded points at every manhole. In buildings not having iron frames there is a copper neutral, but in such cases the company advocates grounding at all possible points to the water piping of the system in the building. In any event, the copper in the neutral is always sufficient for carrying the current. The grounding of the manholes was an extra precaution which probably was not necessary. Mr. E. V. Matlack, of St. Louis, said that there was a similar system in St. Louis, the voltage, however, being 240-480. The only neutral is the lead sheath of the two-wire cable, while in houses a three-wire circuit is carried as usual. The system has been operated successfully for the last three years without any trouble.

In the discussion of the twin arc lamp it was brought out that the two sets of carbons are in series, the current being 2.5 amp. It was acknowledged that the type of lamp could be improved, but in its present form it gives satisfactory service. The reason for adopting the lamp was that if a customer needed only one arc lamp and the ordinary type were installed, he would have to pay for the current consumed in a rheostat of some similar device. The energy in the lamp is 575 watts, which is the same as would be used in one arc; in one case there is lesser current with two arcs in series, whereas in the other case there would be greater current and lesser voltage.

THE LUMINOUS OR FLAMING ARC.

Mr. Welles A. Holmes read a paper describing the magnetite arc lamp, concerning which an article appeared in these columns last week from the pen of Dr. C. P. Steinmetz. From the paper it would appear that the 320-watt magnetite arc lamp gives slightly more light than a 340-watt open arc or a 460-watt, series direct enclosed or alternating enclosed arc. It is claimed that the main advantage of the lamp is the uniformity of light distribution from it. In the case of the 460-watt lamps the average readable distance from the lamp is 267 ft., while with the 320-watt magnetite lamp this distance becomes 325 ft. The magnetite sticks cost about five cents apiece, and there is no expense for inner globes or washing the same, while the outer globe is of the standard type. It is stated to be necessary to have a perforated globe pan as the lamp is dependent on some slight draft to carry the products of combustion up the chimney; stopping this draft would result in coating the globe with the red oxide given off by the magnetite stick. The life of ½-in. sticks in the lamps used by Mr. Barnes in his station at Watertown, Mass., varies from 63 to 95 hours, and the ⅝-in. sticks have an average life of 182 hours with a maximum of 211 hours. With ½-in. sticks an average life of 100 hours has been obtained.

In reply to an inquiry concerning the coating of globes with red oxide, Mr. Holmes said that at first the holes of the globe were on the side and when the wind blew the oxide was caused to collect on the globe. Experience has shown that the lamp needs a direct upward draft; with the lamp now used the globe opening is indented and has holes drilled in the indented portion so that a side wind cannot get into the globe pan, but must come up from the bottom; this has remedied the difficulty and there is no further coating of the globe with red oxide. The quality of the light depends upon the composition of the magnetite stick and may be varied over a considerable range. In reply to a question he said that the burning of the lamps is in no way affected on windy nights. There is no consumption of the upper electrode, the magnetite stick alone being consumed. The public is very well pleased with the character of the light, and recently after a visit to a town by the mayor and council of another city, the lamp was specified for use in that city. Mr. John F. Hillman referred to the superior street illumination given by the magnetite lamp. With the best 6.6-amp. series direct-current enclosed arcs or the best 7.5-amp. series enclosed arcs, the distance at which a certain line on a luminometer card could be read was 257 ft., while with the magnetite lamp the distance becomes 300 ft. Referring to the amperage of the lamp, it was said that the determination of this was quite a problem. If 6.6 amp. had been used at 80 volts, the same as in the enclosed arc system now operated, there would have been a tremendous amount of illumination, almost like that from a miniature searchlight, except that the light would have been radiated from all four sides. It was finally concluded to adopt an amperage giving the standard illumination as it is to-day; and after getting a little bit better illumination at a distance due to the high efficiency of the lamp and its ability to throw the light horizontally, it was determined to use 300 watts and give the central station the benefit of the difference.

STANDARD RATING OF INCANDESCENT LAMPS.

Dr. Bell, in reporting for the Committee on the Standard Rating of Incandescent Lamps, said that at present primary standard lamps can be procured from more than one concern and in general the conditions relating to standardization of lamps have become such that it is hardly necessary to make an extended report. He feels that the work of the committee was pretty much accomplished when the time came when standard lamps could be easily obtained and a general understanding was arrived at as to what would be desirable in the rating and measuring of lamps, and consequently asked that the committee be discharged. He recommended that in the case of reports of technical character there should be closer co-operation between members of the Association. A proper method of doing work of this kind would be to send to all members of the Association a circular asking for detailed statements of conditions as they find them, and the answers should then be digested and printed as a confidential document, so that every member of the Association would know what the other members were doing. At a following convention a special or general committee could report on the data thus obtained and every one who had participated in gathering material for it could then discuss the situation to the best advantage.

A ONE-HUNDRED-MILE TRANSMISSION LINE.

Mr. Robert Howes described the transmission plant of the Washington Power Company, of Spokane, Wash. The transmission line is 98 miles long to the farthest sub-station, and has three short branches at present. It is supplied with power from two Y-connected, 2,500-kw, 4,000-volt, 60-cycle generators driven by water turbines, the current being stepped up by transformers with taps giving a choice of 60,000 or 45,000 volts line pressure. In crossing a swamp the poles were set on a cluster of five poles, the center one being driven 6 ft. lower than the other and thus furnishing a socket, in which the line pole was firmly clamped with heavy iron bands. No. 2 B. & S. medium hard-drawn copper wire is used. At present unity power factor is usually reached with a load of 1,500 kw, the current in the line being then about 18.5 amp. The line has been in operation for over seven months, during which time the circuit-breaker has been tripped eight times. In two cases this was caused by accidental short-circuits on the line made by the company's workmen; in four cases the cause was short-circuits on the secondaries of customers, and the other two cases were from unknown causes. The total time power was cut off by these troubles 32 minutes.

After reading his paper, Mr. Howes stated that since it was written they have succeeded in holding the voltage at Spokane practically steady, there being a variation not to exceed ¾ volt above or below normal on a 116-volt basis, and at the far end of the line the variation was cut down to a trifle over one-half. This was accomplished by means of the installation of a voltage regulator. A controller was then installed on the induction motor at the far end of the line, which cut down the variation another half. In reply to an inquiry he said that power had never been cut off except to cut in substations, at which times advantage was taken of the opportunity to renew insulators which had been broken by boys throwing stones and shooting rifles at them, making targets of them at rifle practice. In reply to another inquiry he said that they have had a number of severe lightning storms, which are much more frequent in that locality than in the Eastern and Middle States, but they had never experienced any trouble from lightning. During one storm, however, the insulation of a transformer for operating high-tension circuit-breakers in the sub-stations was punctured, which caused a shut-down of ten minutes. This was just before another shut-down of nearly an hour caused by a road supervisor putting several pounds of dynamite under a stump of a tree and projecting it through the wires. Dr. Bell called attention to the fact that people apparently expect of induction motors a greater degree of immunity from troubles produced on the line, and with others that motors are heir to than in the case of direct-current motors. Large induction motors should have the starting rheostats very carefully designed and this is usually not done, the lower steps of the starting rheostats in three cases out of four not being made for the fine gradations that are necessary. With proper attention to the starter relatively little trouble will be encountered with large induction motors. He believes it advisable to run a little under unity power factor all the time, never giving the current a chance to become leading and thereby introducing oscillatory factors, with magnetizing and demagnetizing action on the generator acting in quicker succession in response to changes in load. Mr. W. L. Abbott related some experiences with a 9,000-volt line in Chicago nine miles long with which they frequently have trouble. It was put out of operation once by lightning, twice by boys with hay bailing wire, in one case by a trace chain thrown over the line and again by some one who needed the copper.

GROUNDING THE NEUTRAL OF HIGH-TENSION, HIGH-POTENTIAL ALTERNATORS.

A paper by Mr. George N. Eastman on the above subject (to which we refer editorially in this issue) has for its object to show that any advantage which may be obtained by operating an alternating current insulated from earth, will be more than offset by the liability of obtaining high potentials relative to the earth. The study of the conditions was made on the plant of the Commonwealth Electric Company, of Chicago, and the paper is illustrated with diagrams showing the relations of the several voltages existing in connection with grounded and ungrounded circuits. Mr. Eastman considers that a proper method of grounding the neutral of generators is through as low a ground resistance as can possibly be obtained, in this manner fixing the maximum potential which can be obtained between a system and ground at the normal potential which will exist between the neutral of the generator and its phase terminals. The systems of the Chicago Edison Company and the Commonwealth Electric Company of the same city have been operated with a ground for a period of four years, during which they have apparently been entirely free from the high-potential breakdowns that have occurred on other systems of a similar character operated free from ground.

Mr. Hallberg said that the Cincinnati Gas & Electric Company had operated a system during the past four years similar to that referred to in the paper and with unquestioned success from the practical point of view. He considers it to be by far the most simple and reliable system, and the regulation seems to be everything that could be hoped for. In Cincinnati there has been practically no trouble from lightning, the neutral, if anything, protecting the system from lightning discharges. He recommended, however, that since the neutral is grounded all secondaries should also be grounded.

REMOTE CONTROL OF ELECTRIC APPARATUS.

With the above title Mr. William H. Cole presented a paper describing a system of controlling constant-current transformers connected to circuits of arc and incandescent lamps arranged in single or multiple circuits. As illustrated, the apparatus is shown applied to a constant-current or "tub" transformer. The principle of the device lays in the use of a float connected with the apparatus to be controlled, the float being enclosed in a cylinder to which oil may at will be admitted or withdrawn. The amount of oil, and consequently the position of the float in the tank, is automatically varied in such a manner as to maintain the current constant; the variation in level being produced either by running more oil into the tank or pumping some out of it. In the first case the valve of a supply tank is operated by an electromagnet, and in the second place a small electric motor is started up by means of an electromagnet.

THE ORGANIZATION AND EQUIPMENT OF AN ARC LAMP DEPARTMENT.

Mr. Samuel G. Rhodes described in detail the organization and equipment of a separate department exclusively for the care and maintenance of arc lighting service, in this connection drawing upon experience with the arc lamp department of the New York Edison Company. The paper contains reproductions of seven printed cards and slips used in the system, and gives illustrations of a carbon cutter and punch for cutting washers, an inner globe washing machine, a "Bishop's crook" lamp post and a supply wagon. The method of keeping track of every detail connected with an arc lamp system is described, and the duties of the various classes of employees are detailed. In turning on and off direct-current multiple lamps boys, preferably over 14 years of age and almost exclusively school boys, are employed, receiving $2.50 weekly for 45 minutes actual switching work both night and morning. Three men in charge of the boys cover the entire city of New York.

In the discussion of the paper by Mr. Rhodes it was brought out that during the past several years the arc lighting business appears to have come to a halt. Mr. Gilchrist, of Chicago, said that recently he had noticed a tendency on the part of the general public to use arc lights again, but he thinks this is due to a more strenuous effort on the part of central station people on account of sharp competition from various types of multiple gas burners on the market, and which are a strong competitor to the arc light. Mr. Rhodes said that the advance made in New York has really been the work of the contract department. The lighting engineer is a new departure; when trimmers report that any customer's lamps are acting badly the lighting engineer or one of his assistants is around the next day to remedy any defect. Many people have changed over from the Kitson and Humphrey gas burners, the operation of both of which, especially in the winter time, is very bad. He considers the 3.25-amp. lamp very useful, for if the customer does not want to pay for a 5-amp. lamp he will probably be willing to take a lamp of the lower consumption. Mr. Douglass Burnett, of Baltimore, said that there is little difficulty in getting arc light business now when the solicitation is properly done. The customer should be assisted in locating lamps and sometimes given sketches with a general outline of a scheme for his lighting. For example, he may be advised that for the interior of his store he requires a 5-amp. lamp for every 300 sq. ft. of floor space, the lamp to be located with the arc about 12 ft. above the floor level. For the windows incandescents should be recommended. Arc lamps in the interior of a store will show goods better than anything else to customers, and he cannot produce a brilliant effect in front of the store with interior incandescent lights. In fact, the prospective customer should be advised on every point calculated to make his lighting most effective. He considers that the problem still remains as to how to develop the series arc lamp service.

Mr. Rhodes said that while in the case of large contracts the New York Edison Company does not care for the lamps, yet they keep their eye on the installation and freely offer their service whenever it appears to be called upon. As to maintenance of arc lamps, one trimmer at $14 a week, seven days, will take care of 650 lamps; in the repair shop one man will take care of 2,000 enclosed lamps. In this shop one man at $3.50 a day and the rest at $2 will do the work. Mr. Burnett said that in Baltimore he also used night linemen in the various districts, who were available in case of either an open or grounded circuit and for switching on electric signs and for switching them off again. In reply to a question it was stated that the New York Edison Company and the Omaha Electric Light Company furnish diffusers free to their customers, and Mr. Fleming stated that the General Electric Company will adapt its diffusers to any type of lamp.

LOST AND UNACCOUNTED-FOR CURRENT.

Mr. C. W. Humphrey gave an account of the method used by the Denver Gas & Electric Light Company for determining the losses, known and unknown, from alternating and direct-current circuits. The losses are classified as transformer iron losses, primary resistance losses, secondary resistance losses and meter shunt losses. The methods employed by the Denver Company for determining these losses are given in detail, the paper containing reproductions of forms and curves employed in this work. It was found that the greater part of lost and unaccounted-for current was due to thefts. The paper cites an instance where, through proper attention to reducing losses, the ratio of sales to output increased from 59.3 per cent. to 80.5 per cent. In another case, where a feeder was changed from a 1,000-volt individual transformer to a 2,000-volt, three-wire secondary network, there was a reduction in transformer iron losses of over 60 per cent. In this instance the sales were increased to nearly the original amount and the transformer iron loss reduced to about one-half the original amount, though the primary and secondary resistance losses were increased considerably through the increase of the output of the feeder. In the case of a principal business feeder the watts per lamp of output remained about the same for the entire year, while the watts per lamp of sales increased during the same period to nearly double. The sales increased from 41.6 per cent. to 83.5 per cent., the known losses remained about the same, while the unknown losses decreased from 48.4 per cent. of output to only 5.22 per cent. A check meter placed in a district having nine ampere-hour meters and eleven integrating wattmeters showed a loss in the district of 8.1 per cent., not including about 2 per cent. wattmeter shunt losses. The larger loss was principally due to the ampere-hour meters, which do not start on less than two to four 16 cp lamps.

In reply to a question, Mr. Humphrey said that the total accounted for losses of the Denver station were 10.8 per cent. of the output. In the month of December the sales of output were 85.3 per cent.; the current loss and unaccounted for was 5.2 per cent. and the loss accounted for, 10.5 per cent.

ECONOMY IN MINOR STATION SUPPLIES.

In his paper with this title, Mr. Edgar B. Greene confined himself to a consideration of stations of minor size. In his station there is a course of training which starts a young man as an apprentice either in the steam or electrical side of the plant, and gives him a thorough training in all branches of the work. There is no definite period for this course, the apprentice being promoted as fast as his ability will warrant, there being a distinct understanding that each person must earn his promotion or stand aside for the next man. A number of the apprentices take a course in correspondence schools and this method of education is strongly endorsed. The paper refers to a number of minor economies such as standardizing pipe nipples and valves, using tubing in steam hose for use in cleaning boiler tubes, and a home-made arrangement for bending tubes is described. A lathe has been installed for making simple repairs. The ashes and cinders are carted away free by a railroad company and others having use for them. Arc machine brushes are made from strips of hard-rolled copper .01 in. in thickness; four of these are soldered and a phosphor-bronze strip .02 in. thick is used as a stiffener. All oil from the engines is drained by gravity direct to the oil house, where it is filtered by a home-made apparatus. Defective coils of arc lamps and Thomson recording wattmeters are rewound in the station, as well as all transformers. In reading the meters the routes of the men are changed monthly, and different men instead of the same man are used for this service. After the inner globes of enclosed arc lamps are washed they are tested on a ground steel plate for the closeness of joint and then fitted to the holders, the lower holder being trimmed in the station. At least three days' supply of inner globes are always in course of cleaning or washing, which keeps two days' supply ready for use. With a new man the average life of the inner globe is about 800 lamp-hours for the first month and afterwards from 1,400 to 1,500 hours; the number of lamp-hours per carbon is found about 10 per cent. shorter with a new man on the first month.

In the discussion of Mr. Greene's paper, Mr. N. L. Abbott, of Chicago, said that he knows of nothing which will introduce discord in the operating force so promptly and so continuously as placing an outsider in one of the higher positions over the heads of men who have worked faithfully for years. He has known of cases where discord thus produced has been so great that it was necessary to discharge the entire original force. Concerning oil filtering, he considered there were two functions to be performed, one to remove the grit and the other to remove grease and water from the oil. By removing the water and grease in the settling chamber, he has found there is no need of a filtering material in the oil filter. In reply to a question Mr. Greene said the tubing referred to as prolonging the life of steam hose is the Greenfield flexible tubing made by the Sprague Company, a size being used which will fit neatly in the hose. Mr. M. A. Maxwell, of Easton, Pa., said that he found the life of inner globes to be from 5,000 to 6,000 lamp-hours, and 50 per cent. of the globes replaced are broken by boys. Mr. Greene said that standard Edison fuses are carried by his company in stock for free renewals.

THE GAS ENGINE FOR CENTRAL STATION SERVICE.

Mr. E. E. Arnold contributed a lengthy paper entitled "Notes on the Internal Combustion Engine as Applied to Central Station Service," in which, after briefly outlining the theory of the gas engine, he gives data as to test performances and describes and illustrates a number of central stations equipped with the Westinghouse gas engine. A table gives the results of tests for a large number of gas engines of this type. The best result was on a machine in a Madison (Wis.) central station, which showed a consumption of 9.6 cu. ft. of gas per hp-hour, the gas having a calorific value of 1,050 B.T.U. It is stated that the average efficiency of a producer gas plant may be taken at 80 as a conservative figure. A test is cited of a 75-kw gas engine operating from a Mond producer plant, which during two years' continuous operation showed a consumption equivalent to 1.05 pounds of cheap slack coal per indicated hp-hour. A table is given showing that a 2,000-kw gas engine plant can be run for $3,724 a year less than a steam plant, the higher cost of the gas engine equipment being taken into consideration. In the Bradford (Pa.) central station a gas engine reduced the fuel cost from $9,000 to $3,000 per year. At Madison, Wis., a gas engine plant delivered a kilowatt-hour at the switchboard at a cost of fuel more than ⅓ less than that required for running a steam plant.

TEST OF A 5,500-HP COMPOUND ENGINE AND GENERATOR.

Messrs. J. B. Andrew and W. F. Wells gave the data of a test of one of eleven three-cylinder, 5,500-hp vertical compound engine units installed in the Waterside station of the New York Edison Company. The method of test is described in detail and much of the data are plotted in the form of curves. The test showed that for outputs of from 2,500 to 4,500 kw the steam consumption varied between 17.12 and 18 pounds per kw-hour of net output at the generator terminals. The ratio of the net electrical horse-power to the indicated horse-power varied from 94.5 to 95.2. The best test showed an economy of 11.93 pounds of water per indicated hp-hour or 16.78 pounds per kw-hour. The tests indicated a decided disadvantage in the use of a receiver reheater and steam jacket in this type of engine. The curves show an almost absolute uniformity of economy for a considerable range on either side of the normal rating. Increasing the vacuum from 25.3 to 27.3 in. decreased the water consumption only .06 pound, whereas increasing the receiving pressure from 21 pounds to 36.8 pounds, or changing the distribution of load from about ⅖ on the high-pressure cylinder and ⅗ on the low-pressure cylinder, to about equal load on all three cylinders, decreased the water consumption .25 pound.

THE STEAM TURBINE.

Mr. Francis Hodgkinson contributed a paper entitled "Practical Notes on Steam Turbines," in which, after discussing the principles of this type of prime-mover, brief descriptions are given of the De Laval, Stumpf, Curtis, Zoelly and Rateau turbines, the remainder of the paper being devoted to the Westinghouse-Parsons type. This type is described in detail and a number of curves are given of economy tests. A considerable portion of the paper is devoted to foundations and power plant designs for Westinghouse-Parsons turbine electrical equipments. It is stated that at present 43 turbines of the Westinghouse-Parsons type are in operation or under erection in this country, ranging in size from 400 to 2,000 kw, and aggregating 27,000-kw capacity. There are also 69,400 kw in turbines under construction at East Pittsburg in all sizes up to 500 kw. Including machines in the course of construction, the total is 111 machines, aggregating 96,400 kw, or an average of 868 kw per unit.

The papers by Messrs. Andrew, Arnold and Hodgkinson, and the report of the Committee of Investigation of Steam Turbines by Mr. Eglin, were discussed together. In opening the discussion, Mr. Ralph D. Mershon said he noted that in the plant on which Mr. Arnold gave figures, nothing was allowed for relay capacity, and if this were done it would mean a greater investment to the disadvantage of the gas engine. He has found that most gas engine builders rate their engines at or near the maximum load they will carry, whereas the steam engine is rated so as to have a considerable overload capacity. He considers that the gas engine should be figured as having a less efficiency at lighter loads, as compared with the steam engine. Referring to the figures given by Mr. Arnold as to cost per kilowatt of steam and gas installations, namely, $100 and $125, respectively, he thought that the figure for the gas engine should not be under $150 and nearer $175. Mr. Doherty said that the serious drawback in gas engine development is in securing economical and satisfactory transformation of the heat energy of coal into gaseous energy. Mr. H. G. H. Tarr spoke of the reduction of cost to be obtained in the generation of gas through utilizing the by-products. In one process, if the coal is worth $2.50 per ton, the by-products reduce the cost to the equivalent of $1.50 per ton, these figures being applicable to larger plants of, say, 50-tons capacity in 24 hours and above. A producer using bituminous coal will cost from $17 to $20 per hp. Mr. W. R. Gardner suggested that peat might possibly be used to make a producer gas at low cost. Mr. R. H. Rice, of Lynn, Mass., in answer to a request, gave a description in detail of the Curtis turbine. Up to and including 300 kw this turbine is constructed on the horizontal type and on the vertical type for capacities above. He stated that tests under actual working conditions have shown that the turbine maintains its efficiency with variable loads. Moreover, the turbine retains its original economy as long as it is operated, while the steam engine is stated to rapidly lose in efficiency due to the wear of its reciprocating parts. All large Curtis turbines are made now with four stages. He cited a case where only two reciprocating engines of 500-kw capacity could have been installed in a certain power house, where five turbines of the same size were readily located. Mr. H. L. Doherty spoke highly of the prospects of the gas engine, and said that to-day practically every authority on thermodynamics believes the ultimate prime-mover will be the internal combustion engine. In his opinion the steam turbine will be left behind by the internal combustion engine, which will unquestionably be the eventual prime-mover. To get the best efficiency in the gas engine it should be operated at its maximum capacity, since the losses are 25 per cent. of the capacity, no matter what the load. Gas engines cost more per horse-power at the start and the fixed charges are consequently heavier. It is, therefore, desirable to operate the gas engine the longest possible number of hours, and an ideal arrangement would be to use a gas engine to take care of that portion of the load which is on 24 hours a day, the variable load being taken up by steam engines. He endorsed a statement by Mr. Arthur Williams that the present gas engine is relatively no better developed now than the steam engine was during the life of Watt, and he believed the gas engine has wonderful possibilities ahead. He thought that the question of the gas producer is not receiving in this country the attention which it deserves and which is being given to it in Europe. As to the smaller space occupied by the steam engine, in his work he had found that he could not always avail himself of the lesser space indicated by the turbine without the use of a system of steam piping that would not be good engineering practice. Several methods have been proposed to reduce the space occupied by boilers. One is to have the boilers installed back to back, giving a double boiler room with the firing door on the side, the steam piping being led from one firing alley to the engine room. Another plan is to build the boilers with the firing doors at right angles to the turbine and have short alleys running up to the groups of boilers. Another way is to design a special boiler having little width and considerable depth, this probably involving a vertical boiler. Another method suggested but not looked upon with favor was to put the boiler room on each side of the turbines. As to condensers, Mr. Doherty says he has never been able to satisfy himself that he cannot get a higher vacuum from a jet condenser than a surface condenser, and he hopes next year to have some definite figures on this subject. The question of superheaters is a rather serious one for it is difficult to control the degree of superheat and the tubes burn out.

Mr. Arnold, in referring to Mr. Mershon's remarks concerning the rating of gas engines, said that these are ordinarily rated at a brake horse-power of 15 to 20 per cent. under maximum capacity. Steam engines are rated on their indicated horse-power with, say, 50 per cent. overload, but the difference between indicated and brake horse-power amounts to considerable, and the actual capacities of the two types of engines approach more closely than would ordinarily be supposed. As a lighting station has ordinarily a 20 per cent. load factor, the relay capacity is well taken care of in the way the units are laid out in the case Mr. Mershon criticises. Smaller gas engine units of approximately the same efficiency as large gas engine units, and the smaller gas engines, are notably more efficient throughout their range of load than the steam engine. As to the relative efficiency of the gas engine at light loads, he referred to a curve in his paper showing that at half load the brake thermal efficiency of the engine was 21 per cent., while that of a steam engine of the same capacity would only have a corresponding efficiency of 10 per cent. As to the depreciation and life of a gas engine in comparison to the steam engine, experience points out that the former quite holds its own with respect to depreciation, though it will perhaps be found that it costs slightly more for horse-power repairs than the steam engine equipment, excluding the more intricate designs of multiple-cylinder, releasing-gear steam engines using superheated steam. He cited a lighting station having a 24-hour service equipped with 800 hp rated capacity in gas engines in five units, complete repairs for which in the year 1903, including repairs to igniters, cost only $102, or something less than 13 cents per hp per year. In reply to an inquiry he said that all plants referred to in his paper are connected with alternating-current generators operating in parallel, and many of the plants are giving 24-hour service. He referred to a 3,000-hp gas engine cement plant which operates 24 hours a day and has been in service about four years. In reply to a question, Mr. L. R. Alberger said that if hot well water is kept away from the atmosphere it is liable to keep its temperature better, while it has been shown that in this case there is less likelihood of corrosion taking place in boilers.

THE MECHANICAL STOKER.

Mr. Edwin Yawger read a paper entitled "The Mechanical Stoker and the Human Operator," in which he pointed out the various factors which should be considered with respect to the introduction and use of the mechanical stoker. He considered that no builder of stokers should put in his apparatus unless he has submitted to him a complete furnace design to enable him to adapt the stoker to the particular case. The paper is principally devoted to practical considerations relating to the operation of boiler plants.

Mr. C. H. Parker said that the higher the temperature of a furnace fire, the better the furnace efficiency. Flue gases analyzed with low fire temperature show a large excess of oxygen. When the grate combustion is run up to 40 or 50 pounds per sq. ft. rate, the excess air kept is brought down something like 30 to 40 per cent., and the fire is a dead white. Better economy may be obtained by reducing a grate area and using a greater number of pounds per square foot, and also per square foot of heating surface. Mr. R. S. Hale, of Boston, said that after analyzing a great many boiler tests he had reached the conclusion that, other things being equal, the less draft used the higher will be the efficiency. If it is a question of getting a greater capacity, then of course a greater draft must be supplied. or if a grate surface is cut down more draft must again be supplied. He disputed the statement of Mr. Yawger that the same volume of gas at the same temperature will give up more of its heat when passed rapidly over a heating surface than when passed slowly. On the contrary, better efficiency is secured by passing the gases more slowly over the heating surface. One reason why the best efficiencies are gained with a low draft is that this implies more careful firing in order to keep up the capacity, and hence reduces the amount of air used, thereby reducing the loss of heat in the waste gases; and since the gas is passed more slowly over the heating surfaces, they give up more of their heat.

AWARD OF DOHERTY MEDAL.

Dr. Schuyler S. Wheeler, chairman of the committee on the award of the Doherty Gold Medal, said that of the various papers submitted on the subject of underground construction, there were two excellent ones, one by Mr. W. P. Hancock, of Boston, and another by Mr. Blood, of the same city. While the paper by Mr. Blood was very good and exceedingly well composed, it was unanimously decided to recommend the award of the prize to Mr. Hancock. The president, in awarding the medal to Mr. Hancock, said that his career had been passed with the Boston Edison Company, of which he is now general operating superintendent, and the designer of the two stations to be visited in the afternoon by the members. In accepting the award Mr. Hancock said he wished there was a greater engineering interest in underground construction. The subject is an extremely important one and should be given close attention. The distribution system should be entirely reliable or the reputation of the company will suffer, and the construction should be such as to keep the operating and repair charges as low as possible in the future.

CENTRAL STATION AUXILIARY ICE PLANTS.

Mr. C. L. Wakefield presented a short paper entitled "Electric Light and Power Plants in Connection with Ice Plants," in which he gave the result of correspondence with about 50 plants supposed to have an ice plant auxiliary. The results showed that very few of the plants were actually so equipped, and with three exceptions, where there are equipments they have been installed without any particular purpose. In his station a 300-kw alternating-current plant operates a 100-ton ice-making plant with the addition of one oiler and one fireman to the regular force. The fuel cost per ton of ice varies from 350 to 700 pounds of coal, depending upon the calorific value of the fuel and the manner of its use.

Mr. Scheuck thought that it was a bad plan for electric light companies to operate ice plants or enter into other classes of industry, excepting steam heating, for the reason that it was likely to antagonize municipally influential persons who might be interested in competitive ventures.

DECORATIVE AND SIGN LIGHTING.

The report of Mr. Arthur Williams on this subject is presented in sumptuous printed form and consists principally of views of New York City buildings and interiors, and reproductions of letters printed on toned backgrounds. The illustrations are mostly views of facade lighting of theatres and other buildings, with some views of interior lighting, the most striking being a representation of the Waldorf ballroom on the occasion of the Edison A. I. E. E. dinner. The letters are principally reports from electrical companies on the subject of decorative and sign lighting. The mechanical execution of the brochure does much credit to the press of the New York Edison Company.

ADVERTISING METHODS.

The report of Mr. La Rue Vredenburgh on this subject is bound in an illuminated cover and relates principally to the methods of advertising that have been employed by the Boston Edison Company. Reproductions are given of a large number of newspaper advertisements and of electrical signs soliciting central station business, and the text points out methods pursued by several of the larger companies in soliciting business.

The reports of Messrs. Williams and Vredenburgh papers were discussed jointly. Mr. Scheuck said that methods which might pay in large plants could not be afforded by companies in smaller cities. Mr. Williams and Mr. Vredenburgh's methods were undoubtedly of great efficacy for the large companies, but there were only a few companies in the United States which could afford them. He was connected with several plants in smaller cities, these plants doing both railway and lighting business. He had found one of the best methods of getting new business was to print small booklets and to supply them to metal holders in the street cars each day. In a town of 50,000 inhabitants he had begun with an issue of 4,000 booklets a week and had had to increase the number. The booklets contain humorous items interspersed with advertising arguments; he found that people would take these booklets home and that they had been the means of increasing his lighting and power business. Another method of extending power business is to go to small factories and shops already equipped with motors, but not intelligently so; to re-equip them so as to secure higher operating economy and take photographs of the meter bills before and after the change, using these photographs as advertising material. He advocated making very low rates to stores for electric signs, show window lights, etc., and taking special care to see that the stores maintained their signs and show window lights in good condition. Mr. Scheuck also pointed out that the lighting company's office should be in a good location and well illuminated at night in order to make a good impression on the citizens. Mr. Converse D. Marsh disagreed with Mr. Scheuck as to methods of getting new business. He thought that methods of getting new business should be the same in character in smaller plants as in large ones, differing only in degree. Promiscuous distribution of booklets he did not consider efficacious. Solicitors could not know who had been reached by the booklets, so that a follow-up system could not be applied; the booklets alone certainly would not bring a man up to the point of signing a contract. Mr. Burnett also disagreed with Mr. Scheuck. He was connected with a company in a city of moderate size and had obtained good results by furnishing free electric signs in order to obtain the resulting business. President Edgar, in response to an inquiry by a member, said that the Boston Edison Company spent 5 per cent. of its gross income in advertising and soliciting new business, this amount being about equally divided between the two branches.

FACTORY ELECTRIC POWER.

The report of the Committee on Purchased Electric Power in Factories, consisting of Messrs. W. H. Atkin, chairman; S. Morgan Bushnell and G. W. Brine, gives the result of inquiries made by circular letter concerning the use of electric power in factories. The letters were sent to all of the members of the Association and asked for answers to 13 questions relating to the charge for power, kind of factories supplied, increase of power business, decrease of production cost from use of electric power, kind of electric drive, amount of power sold, etc. To 462 circular letters sent out 61 replies were received. Of these 19 reported no sales of factory power, 11 either gave no information or answered but one or two questions, and 31 replied more or less fully. The average increase of power business of 24 companies reporting was 37 per cent., a larger amount of increase than the lighting load. The rates reported range from 2 to 15 cents per kw-hour, the usual range being from 4 to 10 cents. Among the conclusions of the report are the following:

The sale of electric power by central stations to factories has been limited largely to such industries as have to carry on their business in the centers of cities or towns where space is costly and where the trouble and danger of steam engines become large factors. The great industries of boots and shoes, cottons and woolens, usually produce their own power.

Among printers there is a large patronage from "job shops" and a good proportion of the newspaper offices, but practically none of the book printers, whose "runs" are long and whose "make-readys" are comparatively short.

The committee considers that the best method to increase business is to educate the prospective customer. Although electric power has been in use for 15 years, it is not yet the first power of which a man thinks when he is about to start a new factory. If the central station could have its solicitor on hand to explain the advantages of electric drive over mechanical drive before the prospective customer has purchased his gas engine or steam engine, or made his contract for power from a belt, a great amount of business might be obtained which is lost simply through unfamiliarity with electric power on the part of the power-using public. In this connection it is of the highest importance that the solicitor be thoroughly conversant with different manufacturing processes, and be a man of great power of observation, so that he can take in the situation quickly and give the customer the needed points which will "tell" and turn the scale to electric drive supplied from central station.

After a customer has been secured he should not be left to his own resources, but should be advised as to the number of motors to purchase and their arrangement. Careful attention to the details of installations at the time the motors are purchased will effect economies, and these will go to the credit of the central station service. The customer is naturally quite reluctant to buy several motors, when, so far as he can see, one will do the work just as well; but the solicitor should have at hand facts and figures that will prove conclusively that the extra motors will return a good dividend upon the investment, and that with the individual motor equipment or the group drive, the central station can supply power more cheaply than the customer can produce it himself.

One great point of economy which should be looked after is the use of the electric elevator in place of that operated by steam or hydraulic power. In many factories may be found a slow-speed freight elevator driven by belts from the main shaft. This can always be changed over and connected to an electric motor without calling on the elevator makers and at comparatively small expense. Another important feature in central station service is the facility with which any single department can be run overtime. This often avoids the employment of inexperienced help, and enables the manufacturer to respond more promptly to any unusual demand. Another exceedingly important factor in the advantages of electric power is the ease with which a plant can be enlarged by merely buying additional motors from time to time, instead of taking out and discarding an overloaded steam plant and putting in a new one at enormous expense, or at least adding long lines of shafting and belting.

The ability to move machines about, taking the tool to the work, instead of the work to the tool, is often a great advantage in large establishments, and this may be done with the greatest facility when tools are directly connected to electric motors. The time saved by this arrangement in shops handling large masses of metal would pay a very large dividend on the investment in motors. The cleanliness of a shop supplied with motors instead of with shafting would be a revelation to one who was not familiar with the results which such a change in power produces.

HEATING FROM CENTRAL STATIONS.

The report of the Committee on District Heating, consisting of Messrs. E. F. McSherman, D. F. Magee and C. M. Maunsell, gives the result of an inquiry made among central stations operating steam and hot water systems. Of 100 companies addressed, 52 replied, including 36 operating steam and 16 operating hot water systems. The report gives in tabular form the replies to the 24 questions propounded. The conclusions of the committee are that as a whole it seems clear that the companies now in the heating business are in general making money. Out of the 35 steam systems 31 state and show, by the figures returned, that they are well pleased with the investment. Out of 15 operating hot water systems, 11 are satisfied and 4 are not. The best financial showing is made by those companies basing their charge on readings by meter and cubic feet of air space, which insist on the use of economizing coils, inspect and supervise the installation of buildings and refuse to connect or give service to poorly-designed heating systems; and which keep separate accounts of heating and electrical revenues and expenses, and recognize the value a heating system has as an auxiliary to electric light and power supply. It is at least a coincidence that the companies making the poorest financial showing are those that, from a lack of knowledge of what they are actually doing, are unable to make definite or explicit replies to some of the questions asked.

Replies to one of the questions indicate that there is no difficulty in securing or retaining heating patrons, which would seem to indicate that in most cases companies are not receiving as much for heating service as it would cost the customer to supply himself, and consequently it would seem that prices might properly be advanced. The comparative cost of steam heating and coal heating in buildings does not seem to enter into consideration when central station heating service has once been used. The important matter of depreciation has not had the consideration that should be given to it; only 21 of the 52 companies reporting have seen fit to provide for this. Most companies report low cost of repairs, one that has been in business for six years reporting only 2½ per cent. on mains and services. The question of returning condensation to the power house seems to be one related to local conditions. Very few express themselves favorably on constructing a plant for this purpose, though a few are much in favor of it, probably owing to the local situation. The replies seem to indicate that district heating is now a success and could be made more so if central station managers were to co-operate with the committee for the general good. The paper gives the full text of the replies received from all of the central stations which reported.

In the discussion, Mr. McCabe, in answer to an inquiry, said that of the fifty-two companies that had replied to his inquiries only five or six had made any charge to cover depreciation on mains, etc. One company which had been in the heating business fifteen years charged 2½ per cent. for depreciation. Another company which had been supplying heating service for eight years made no charge. Mr. McCabe thought that the depreciation should be taken into consideration, but that it would be very small. He also pointed out that the supplying of heating service enabled an electric light plant to get lighting business in office buildings and other large establishments, which, if they had to maintain heating plants, would also operate their own lighting plants. Mr. Williams, of the New York Edison Company, said that his company had met this argument usually by offering to furnish labor, fuel and supplies for operating the heating plant and to operate the plant at a lower rate than the records of the office building or other establishment had shown the heating service to cost. He said that his offer had never been taken up, but that it had always proved efficacious in combating the argument advanced by the building owners.

OFFICE METHODS AND ACCOUNTING.

Mr. Frank W. Frueauff, in his report on office methods and accounting, confines himself to an account of the methods used in the offices of the Denver (Col.) Gas & Electric Company. The subject is considered under the following heads: Complaints, bureau of information, meter reading, office mistakes, card records, accumulative reports, receipting machine, adding machine, self-adding sheets, slide rule, Thatcher calculator, tube system, tabulating machine and analysis of steam generation. Reproductions of several forms are included in the report. Mr. Frueauff favors the plan of apportioning the cost of operation to the class of current made and of separating fixed and variable costs. The expenses occasioned in manufacturing and distribution for any one class of current should be kept distinct from those incurred in another, so that the actual cost of manufacture and delivering arc power and alternating current may be known separately. The cost for any one class should also be separated to show the costs that are fixed as distinct from those that are variable. For example, station foremen, meter department, shop expenses, etc., are practically a fixed expense, not varying notably as the business increase or decreases. Boiler fuel, firemen, lamp renewals, carbons, etc., vary with output, and under a third head may be included meter, arc lamp and service repairs, meter reading expense, collection and office salaries. With the cost for any class of current separated into these three divisions, it is possible to know just what results are being obtained, and this method is particularly valuable in figuring rates to be made to secure new business. For example, in figuring to take on a long-hour burning customer, it is known from the figures of cost that the fixed cost will not be materially increased nor the consumer's expenses, and that only the output cost will be increased.

At the close of this discussion, the president appointed the Committee on Nominations, consisting of Messrs. P. G. Gossler, New York; D. P. Robinson, Boston; Irvin Butterworth, Denver; W. C. L. Eglin, Philadelphia, and F. E. Smith, Somerville, Mass.

Mr. H. L. Doherty, chairman of Committee on President's Address, then submitted his committee's report. The committee warmly commended the suggestions in the president's address relating to methods for advancing the interests of the Association. It recommended taking quarters in the Union Engineering Building, and suggested the appointment of a reporter to collect data on the thawing of water pipes by electricity in order to deduce something like standard methods for the work and to arrive at a satisfactory basis of charge for such service.

CENTRAL STATION STANDARD INSTRUMENTS.

In a paper entitled "A Proposed System of Standard Instruments for Operating Companies," Mr. H. P. Davis, after sketching the extreme desirability of accuracy of central station measuring instruments, and consequently the necessity of reliable standards for calibration purposes, suggests that a remedy for the present unsatisfactory condition in these respects may be offered by the manufacturers of high-grade electrical instruments. Such manufacturers, it is stated, have the equipment and facilities necessary for the manufacture of portable or semi-portable instruments possessing the desired requisites, and for their certification and periodical checking while in use, with trained and experienced engineers familiar with the problems involved and the means for solving them. Would it not, it is asked, be most natural and advisable for such a concern to design instruments of this nature; to offer them upon a fair commercial basis for the use of operating companies; and thus to give the purchasers the benefit of their exceptional facilities for designing, manufacturing and maintaining their accuracy in use?

The service as rendered by manufacturers of such standard instruments could be advantageously used to cover their care and recalibration after they were put in the hands of purchasers. All the conditions of manufacture combine to make the manufacturers of such instruments the best able to care for them thereafter.

To render the best service under the plan suggested, the manufacturers of the instruments should make no charge for recalibration and should see to it that prompt return is made to the owners. It might even be found advisable to ask owners to send in instruments to be checked when a considerable period has elapsed without such attention. The owner would be at no expense, except for carriage, and should have no hesitancy in sending his instruments to the maker for attention when desired. The testing departments of operating companies would thus be kept in contact with a standardizing bureau or department, whose certificates should rank in excellence with those of the best and most favorably known government bureau or the most famous standardizing laboratories. It is stated that to render such a system successful requires an instrument far superior to all present types, and to cover the field properly the assortment should be made up of voltmeters, ammeters and wattmeters. Specifications are then given as to the design of the instruments answering the necessary requirements.

SINGLE-PHASE ALTERNATING-CURRENT MOTORS.

Mr. W. A. Layman read a paper on "Single-Phase Power Motors for Electric Lighting Stations," which treated the subject under the following heads: Reliability of single-phase motors; comparative cost of insulation of single and polyphase motors; single-phase motors on polyphase generators; single-phase motors for lighting circuits; single-phase motors for high frequencies; the desirability of motor load for central stations; the special value of motor load to small stations; the day circuit as a factor in the building up of small towns, and power rates for single-phase motor service. The discussion of the subject was based upon the assumptions that the single-phase motor, except for variable-speed work, is to-day the substantial equivalent of the direct-current motor; that polyphase and single-phase types of motors are not competitive, and third, that simplicity of generating equipment and system of distribution are of paramount importance in the profitable development of central station service.

For large plants having polyphase generators, Mr. Layman suggests that the switchboard be arranged for operating first polyphase feeders for all large power and rotary converter service. Second, single-phase feeders for all general lighting service and for all small power work, the switchboard being such that any single-phase feeder may be switched to either phase of the generator buses; where substations are employed similar switchboard arrangements should be made for polyphase distribution in large units and single-phase distribution for all other kinds of service. Third, independent feeder regulations for all polyphase as well as all single-phase feeders. It is stated that the cost of installation of the single-phase motor is actually much less than that of the polyphase; that satisfactory single-phase motor service can be gotten from polyphase generators, and that single-phase motors can be satisfactorily operated from lighting circuits. The New Jersey Public Service Corporation and the United Gas Improvement Companies are installing single-phase motors up to and including 35 hp and the Cincinnati Gas & Electric Company is adding single-phase motors of 15 or less horse-power capacity and considering larger installations individually on their merits. In Chicago motors of 5 hp or less are required to be single-phase and larger installations are considered individually on their merits. Satisfactory single-phase motors can be made for 125 and 133-cycle circuits. There are a number of instances of central stations giving 133-cycle motor service almost up to the maximum capacity of the plant. The paper includes power rates for single-phase motor service as established in Peoria, Ill., and in Cincinnati, Ohio. In the former place the charge varies from 10 cents per kw-hour up to 100 kw-hours per month to 2.8 cents per kw-hour for over 2,000 kw-hours per month and over; 10 per cent. discount being given on all bills paid within ten days. In Cincinnati the basic rate is 10 cents per kw-hour, with discounts varying from 10 per cent. for 100 kw-hours per month to 60 per cent. for over 800 kw-hours per month, there being an additional discount of 5 per cent. on all bills paid within five days.

Mr. J. H. Hallberg stated that the Cincinnati Gas and Electric Company had had to adopt the policy of declining to connect up three-phase motors smaller than 15 horse-power in order to keep down the fixed charges due to the investment for transformers, meters and accessories. They had found that the use of single-phase instead of three-phase motors within the limits mentioned had effected a very considerable economy in fixed charges and had also enabled the company to supply customers whose service would not have been worth obtaining if it had been necessary to run three-phase lines to them and install three-phase transformers, meters, etc. In the case of elevators and other special machinery requiring heavy starting torque, three-phase motors were still used in all sizes.

WRINKLES.

Vying with the "Question Box" in value to all members of the Association, a new department of the Association's work has been initiated in the form of a collection of notes entitled "Wrinkles," giving an account of practical expedients, home-made apparatus, etc., devised by central station men. The editor, Mr. Charles H. Williams, has been able to collect through correspondence no less than 103 items of this character, occupying 107 pages of the *Transactions*. The character of the matter may be judged from the following titles of some of the notes: Truing engine pins; feed water heater on a gas engine exhaust; a home-made traveling crane; repairing a defective boiler crown sheet; keeping a commutator in good shape without turning or sand-papering; a coil-winding machine; running 9.6-amp. lamps and 6.6-amp. lamps from the same machine; reducing standby losses during light load; transformer testing set for line use; locating breaks in series arc circuits; water rheostat used as a starting box; a special transformer for thawing frozen water pipes—there being several notes on this subject; a novel electric sign.

LARGE WATER POWER INSTALLATIONS.

Dr. F. A. C. Perrine presented a paper on Thursday evening which he illustrated by means of lantern slides, giving an account of the genesis of water power electrical generation and describing briefly some plants of this character installed in this country.

ELECTRIC HEATING.

Mr. James I. Ayer presented a very interesting paper on the subject of electric heating, cooking, etc., which will be again noted in later issues.

Mr. Ayer recommended that the plan adopted with respect to arc lamps should also apply to electric heating, and that kitchens and heating outfits of all kinds should be installed free. This system is carried out by the gas companies with great success. The average kitchen for a family of from four to eight persons involves a transformer capacity of about 30 amp. and 3 kw. The average demand of a family of this kind is about 20 amp. and 2 kw at the cooking hour, or about two-thirds the house service. Most of the load for cooking is over by 6 o'clock, so that at most seasons of the year it would not coincide with the peak load. Mr. Alex Dow, of Detroit, said that in Detroit the peak load is in advance of the general maximum lighting in the residence districts, coinciding with the downtown peak. Electrical cooking would add to the main station peak load, but for winter service only. The cooking load is about two hours per day throughout the year. It does not do to sell cooking apparatus unless they are looked out for. An absolutely clean, smooth vessel is better than the ordinary cooking utensil, and the best one is a type of vessel which clamps solidly to the disk. The conducting cords are a nuisance, and he suggested that they should be passed through a hole in the table as in the case of telephone switchboard cord. The devices furnished by various makers for varying the heats are about useless in the hands of the ordinary kitchen servant. He considers that two heats are practically sufficient—one quick and one simmering heat—and that these can be obtained by a double-throw switch, which when open cuts the heat off altogether. The worst fault to be found with electrical cooking to-day is in the repair bill, which is a very serious matter. Mr. Arthur Williams spoke of the desirability of circulating among electric light users information relating to electric cooking, and said that the New York Edison Company has recently been doing this extensively. He thinks electric cooking apparatus will never give to the companies a large revenue, since its use is confined to short periods of the day, but aside from cooking the late afternoon dinner in the winter months, whatever revenue comes from this apparatus is additional per kilowatt of installation. This in itself should encourage effort toward installing electric heating and cooking apparatus. In the months of June, July, August and September the load will not come on at the peak, and in view of this it might be well to adopt the English method of making a lower charge for the current used during these months. He considers that every large device connected with electric cooking should have an indicator which cannot be removed and which will show when current is on and off; he has known of cases where the colored lamps supplied with cooking apparatus have been turned out and the current left on. In one case the current was left on an electric heater during the entire summer season in the absence of the owner. He cited a case of a large factory where electric irons are used for making hats; the price paid for current is 8 or 9 cents per kw-hour and the cost of this service is almost identically the same as that of the former service rendered by gas. The advantages in the use of the electric heating iron are that the men work faster, thus increasing the output; the factory and the men working there are kept cleaner; the atmosphere is cooler and working with the electric iron is much less fatiguing to the employees.

THE NEW TICKET.

Some little difficulty was experienced in selecting the new ticket. Mr. J. W. Lieb, Jr., was in direct line, but it was realized that as incoming president of the Institute he had already more than he could well attend to. Among those favorably discussed were Messrs. Arthur Williams, of New York; J. B. McCall, of Philadelphia, and Alex. Dow, of Detroit. A fortunate solution of the situation was found in the final willingness of Mr. E. H. Davis, of Williamsport, Pa., to serve. The efficiency and popularity of this admirable central station manager as secretary have made the powers of the Association reluctant to lift him out of that onerous position, but the choice has met with universal approval. The officers elected on Thursday night were as follows: President, E. H. Davis, Williamsport, Pa.; first vice-president, W. H. Blood, Seattle, Wash.; second vice-president, Arthur Williams; executive committee, S. Scovil, Cleveland; A. J. De Camp, Philadelphia; W. F. White, St. Louis.

CONVENTION NOTES.

On Tuesday afternoon a tally-ho ride was given to the ladies through the beautiful suburbs of Boston out to the Country Club as far as the Chestnut Hill Club, where tea was served. The return route lay through Brookline. Several vehicles were needed for the party, and the trip was greatly enjoyed. It was in the hands of Messrs. C. J. Hatch, W. E. Holmes and D. P. Robinson. In the evening a lecture was given in the main dining-room of the Hotel Vendome, on "Historic and Technical Boston," accompanied by lantern slides. The lecturer was Mr. Samuel C. Clough, who did his subject justice in an admirable manner. The technical part of the lecture was prepared by Messrs. L. L. Elden and I. E. Moultrop, the former giving his attention to the electrical development of Boston in general, and the latter taking up more particularly the new Boston Edison turbine station. It was a happy idea thus to fill in an evening in an informational way, and add to the stock of knowledge so agreeably. Everyone was greatly pleased and many compliments were paid to Mr. Larue Vredenburgh on his skill and success as an impresario and lecture bureau manager.

On Wednesday afternoon the whole convention, then about 1,000 strong, was given a steamboat excursion around the harbor, special cars taking the party from the Public Library to the wharf. Lunch was provided on board, and the excellent Salem Cadet Band furnished music. After the circuit of the harbor and out to the seashore line, landing was made at the L Street station of the Edison Company, where all the fine plant was shown in operation. In the new turbine room a dummy turbine of lath and paper was set up to scale on one of the bed plates to show exact size and appearance. On the return voyage landing was next made at the Atlantic Avenue station wharf, where special cars again awaited the party for home. The trip was most delightful and a brilliant sucess, reflecting much credit on the committee, Messrs. Sidney Hosmer, P. Hodges, W. C. Woodward and Prof. H. E. Clifford. Wednesday evening was spent by invitation at a popular concert in Symphony Hall, under the conductorship of Adamowski. The entire lower floor within the rail was reserved for delegates and their friends, and refreshments were also served. The committee in charge were Messrs. P. L. Warner, T. C. Wales, R. N. C. Barnes, George C. Ewing and F. W. Lord.

On Friday, when the practical work of the convention had closed, a number of trips were planned, being scheduled to start at different hours of the day. These included the General Electric works at Lynn, Mr. W. C. Fish; the water power plants at Lawrence, Mass., Mr. R. A. Hale; Salem, Mass., Mr. H. M. Batchelder; Bunker Hill Monument and the Navy Yard, Mr. P. J. Kennedy; Fore River Ship Yards at Quincy, Messrs. C. H. Parker and G. H. Berg; trolley trip, Mr. Paul Winsor; New England Gas & Coke Works, Mr. G. H. Finn; Boston Edison plants, Mr. W. P. Hancock; Boston Elevated system, Mr. Paul Winsor; East Boston tunnel, Mr. R. N. C. Barnes; Harvard College, Prof. C. A. Adams; Massachusetts Institute of Technology, Prof. H. E. Clifford; Simplex Electric Company's works, Mr. E. Morss; Holtzer-Cabot Electric Company's works, Mr. C. W. Holtzer; New England Telephone & Telegraph exchange, Mr. T. C. Wales. In connection with the last-named it must be noted that at certain hours free telephone service to New York was courteously accorded during the convention.

The ladies were by no means forgotten during the meeting. In addition to the entertainments elsewhere noted, and in which they were included, they were given a special tally-ho ride and a splendid run around the suburbs in automobiles on Thursday.

President Edgar is not only to be warmly congratulated on the success and smoothness that attended all his thoughtful and generous provision for the convention—in which an excellent committee co-operated with him—but on the success of the convention *per se*. Note has already been made of the work of the convention, but it remains to be added that no fewer than 1,150 people actually registered, and that of these a record proportion represented the strictly central station element. In fact, nearly 40 States and Territories sent some 400 central station men, from about 200 towns and cities. In connection also with the work of the convention one must commend specially the skillful plans and efforts of Mr. Charles H. Hodskinson, of the Boston Edison Company. One of his wrinkles was an envelope plan, by means of which each delegate could leave his papers, etc., in a numbered pouch just outside the meeting hall as he left and get it again when he entered for the next session. The scheme was a great convenience and worked admirably.

Secretary E. H. Davis and his efficient assistant, Miss H. Billings, had their hands more than full of work, but were greatly gratified at the satisfaction evinced by members at the arrangements and the complete state of the plans, papers, etc. But they were so glad when Saturday came!

Electrical Engineers were present at the convention in goodly numbers, and representative of all ranks and varieties of the profession. Among them may be mentioned Prof. Elihu Thomson, Dr. A. E. Kennelly, R. D. Mershon, J. H. Hallberg, Capt. W. Brophy, P. G. Gossler, Dr. Louis Bell, F. E. Cabot, A. E. Childs, C. J. Field, Dr. S. S. Wheeler, E. R. Weeks, T. D. Lockwood, Dr. P. Pivili, of Milan; Dr. Wm. Habirshaw, R. A. Hale. Educators were also conspicuous, including Prof. C. A. Adams, Prof. H. E. Clifford, Prof. H. B. Smith, Prof. Clarence Feldman, Prof. C. H. Porter, Dr. Louis Duncan.

Large Advertising.—One of the object lessons of the convention week was the appearance of a two-page "ad" in the *Boston Herald* giving a large engraving of the new Boston Edison plant and announcing that after a thorough test of the efficiency of a private plant, that well-known newspaper had reached the conclusion that central station service was better, and that its power and light would be bought hereafter from the Edison system. The capacity of the system was given as 1,380,000 lamps, and it was said that 3,000,000 newspaper readers in and around Boston depended for their daily journals on the ever ready and unfailing service of the Edison Company.

Electrical World and Engineer was represented at the convention by Messrs. J. M. Wakeman, G. W. Elliott, C. T. Walker, W. S. Key, A. D. Adams and T. C. Martin. The current issue of the journal was in demand, not only on account of its articles on the situation in Boston and New England, but because of the interesting historical sketch of what was done at the Boston convention of 1887.

The Technical Press was out in force and in addition to the staff of this journal there were present Messrs. C. P. Poole, C. W. Price, L. Cassier, W. F. Collins, W. E. Keily, F. L. Perry, H. C. Cushing, E. E. Wood, A. E. Clifford, A. L. Rice, J. S. Browning, W. K. Beard, I. A. Bennett, S. C. Cole, C. E. Cornell, Jr., F. C. McDonald, W. T. Hunt, S. A. Goddard, P. S. Dodd, H. S. Tuthill, M. L. Godkin, F. R. White, A. D. Stevens, J. H. Smith, W. F. Hanks.

Mr. E. R. Weeks, of Kansas City, one of the early presidents of the Association, gratified a great many old friends by putting in an appearance. It was the first in some years, and Mr. Weeks was very much impressed, not only with the growth of the body, but with the enthusiasm displayed, equalling, if not excelling, anything he had seen in the past. At the opening session he made a few happy remarks, upon the call of President Edgar.

Mr. F. E. Barker attended the meetings on behalf of the Massachusetts Gas & Electric Light Commission, whose work has been so useful and performed so conservatively.

EXHIBIT NOTES.

Mr. Joseph Sachs, who was attending from Hartford, Conn., has just been awarded the award of the John Scott medal of the Franklin Institute for his enclosed fuse protector, and with blushing diffidence received the congratulations of a host of friends.

Mr. Alex Henderson, who has just returned from South America, appeared on behalf of the conduit interests of the Interior Conduit Company. He was elaborately disguised in a Mexican sombrero and tanned cheekbones.

John A. Roebling's Sons Co. had no exhibit, but were represented by Messrs. F. W. Harrington and G. W. Swan, M. R. Cockey, C. B. Cushing, as well as A. Mann, of Boston. They are said to have distributed souvenirs.

The Westinghouse Exhibit displayed in the parlors on the ground floor of the Hotel Vendome was of especial interest because of the number of new appliances shown for use in electric lighting and central station practice. Much attention was given by the visitors to the Westinghouse type A integrating wattmeter, which presents several essential improvements over the well-known integrating wattmeters of that company. Single and polyphase instruments in metal cases, single-phase with glass case, and master wattmeters of this type in glass cases for central station use in checking service meters, were shown. Models of the mechanism on a magnified scale were used to show the construction of those portions of the instrument which form its distinguishing characteristics. This type of instrument has been adapted for prepayment service, and the prepayment type A wattmeter attracted much attention. A new type of high-grade portable testing instrument excited very favorable comments on account of its superior finish and attractive appearance. Of this type were shown a voltmeter, an ammeter, a single-phase and a polyphase wattmeter and a power factor meter. They are particularly adapted to central station use on account of the unusual range of scale and the long open divisions of equal length. These scale characteristics make the voltmeter, ammeter and wattmeter more readable at all portions of the scale than any other instrument of this kind. The polyphase wattmeter is the only portable instrument of this kind on the market. The power factor meter is also a new instrument. Portable transformers, mounted in finely finished mahogany cases, were also shown with the measuring instruments. Arc lamps included five different types of styles: Series alternating, multiple alternating, series multiple-alternating and direct-current series and multiple lamps, all of the enclosed type and new designs of high efficiency. The fan motors were represented in the exhibit by several groups of these devices, some of which were effectively utilized to keep the room cool. A type B oil circuit-breaker for switchboard use received considerable attention because of its compact form, simplicity and high degree of insulation. A new departure in standardizing methods was foreshadowed by the display of a new series of precision instruments, having the advantages of the ordinary instrument—portability and convenience—combined with the extreme accuracy and permanency of the Kelvin balance. The Westinghouse exhibit was in charge of Mr. R. L. Warner, New England manager of the Westinghouse Electric & Manufacturing Company, who was ably assisted by the Boston men. A number of the officials of the company were in attendance, the complete list of attendants being as follows: Mr. F. H. Taylor, vice-president, Pittsburg; Mr. Arthur Hartwell, sales manager, Pittsburg; Mr. W. H. Whiteside, manager Detail and Supply Department, Pittsburg; Mr. R. L. Warner, New England manager, Boston; Mr. C. B. Humphrey, manager, Cincinnati, Ohio; Mr. W. F. Fowler, manager, Baltimore, Md.; Mr. H. D. Bayne, manager, Montreal office, Canadian Westinghouse Company, Montreal, Canada; Mr. C. W. Underwood, manager, Buffalo, N. Y.; Mr. G. B. Dusinberre, manager, Cleveland, Ohio; Mr. D. E. Manson, manager, Boston; Mr. Andrew Raeburn, manager, Westinghouse Machine Company, Boston; Mr. C. C. Chappelle, manager, Westinghouse Machine Company, Chicago, Ill.; Mr. Y. L. Brinsmade, manager, Westinghouse Machine Company, New York; Mr. H. P. Davis, assistant chief engineer, Detail Department, Pittsburg; Mr. F. F. Rohrer, manager Direct-Current Department, Pittsburg; Mr. C. W. Register, Chicago, Ill.; Mr. J. B. Comstock, Pittsburg; Mr. Henry Watts, Buffalo, N. Y.; Mr. A. Goodby, Pittsburg; Mr. George W. Pulver, Syracuse, N. Y.; Mr. Frank B. Erwin, Syracuse; Mr. O. T. Smith, New York; Mr. C. E. Skinner, Pittsburg; Mr. E. E. Arnold, Westinghouse Machine Company, Pittsburg; Mr. F. E. Conrad, Pittsburg; Mr. Francis Hodgkinson, Westinghouse Machine Company, Pittsburg; Mr. J. H. Smith, Pittsburg; Mr. Edwin Yawger, Westinghouse Machine Company, Pittsburg; Mr. H. R. Stuart, Pittsburg; Mr. R. L. Rathbone, Detroit; Mr. C. S. Jennings, Sawyer-Man Electric Company, New York; Mr. C. G. Wilson, Westinghouse, Church, Kerr Company, Boston; Mr. S. M. Bramman, Westinghouse Machine Company, Boston; Mr. F. F. Breed, Westinghouse Machine Company, Boston; Mr. J. W. Lucas, Philadelphia; Mr. C. L. Abbott, Boston; Mr. E. D. Mills, Mr. M. H. Merrill, Mr. G. M. Bates, Mr. R. S. Brown, Mr. F. S. Perry, Mr. G. L. Osborne, Mr. G. S. Gibbs.

The Sawyer-Man Electric Company, of New York, made its first public display of the "Lumino" lamp. The lamps were used to light a large candelabra in the main Westinghouse exhibit room and attracted very favorable attention because of their brilliancy. The lamp is of 54 cp and shows a remarkably low wattage. A handsomely engraved card, showing the "Lumino" lamp, full size, was distributed to all visitors. A full line of standard incandescent lamps was likewise shown by this company.

Pass & Seymour, Solway, N. Y., the well-known manufacturers of tubes in porcelain and other insulating specialties, were much in evidence in the personages of Mr. B. E. Salisbury, the treasurer, and Mr. John W. Brooks, the sales manager of the company, and Messrs. A. M. Little and Hall, the Boston and New York representatives.

The Electric Storage Battery Company was represented by Messrs. Charles Blizard, sales manager, and J. W. Cook, Boston.

The Standard Underground Cable Company were represented by Messrs. F. C. Crosby, T. E. Hughes, C. J. Marsh, W. C. Waldron.

The Duncan Electric Manufacturing Company, Lafayette, Ind., had an attractive exhibit showing the latest types of their well-known D. C. indicating wattmeters. One of the latest improvements to which special attention was called is the new visual bearing, with threadless jewel post. As the name indicates, this bearing may be readily inspected at any time, and may be quickly removed without unscrewing. Among the other apparatus exhibited were switchboard meters in various designs and finishes up to 5,000 amperes. The exhibit was in charge of Messrs. Thomas Duncan and William H. Sinks.

The Phelps Co., Detroit, Mich., were on hand with an exhibit of "Hylos" in charge of President W. E. Phelps and sales manager, Mr. F. L. Du Broy. "Winking" lamps for sign work were a feature of the display. The new "Lazy Man's" lamp also attracted a great deal of attention. This lamp is operated by a modified knife switch enclosed in a small, compact porcelain case which is attached to covered wires of various lengths. The well-known "pull string" and "turn bulb" types were, of course, shown in great variety.

The Bossert Electric Construction Company, Utica, N. Y., were represented by Mr. F. G. Scofield.

Speer Carbon Company.—J. S. Speer, generaal manager of The Speer Carbon Company, St. Mary's, Pa., spent a day at the convention on his way to Maine for a two weeks' outing.

Mr. John Mustard, who has recently accepted the Philadelphia agency for The Wagner Electric Manufacturing Company, was on hand from the opening session and took full advantage of this opportunity of meeting his many electrical friends.

The Sterling Electrtic Manufacturing Company, Warren, Ohio, distributed an attractive souvenir through Stuart, Howland Co., their New England agents. The souvenir took the form of a tape measure enclosed in a celluloid case on which was data to prove that "Sterling Special" lamps are "sixteen all ways."

Mr. J. P. Gilbert, of The Standard Electrical Manufacturing Company, Niles, Ohio, was on hand, of course, to look after the interests of "Star" lamps.

The American District Steam Company, Lockport, N. Y., was represented by Messrs. Charles R. Bishop and H. C. Eddy.

Doubleday-Hill Electric Company. Mr. Charles Phillips Hill, of the Doubleday-Hill Electric Company, Pittsburg, was much in evidence all through the convention, and justly proud of the enormous catalogue which they have just issued, which marks an epoch in electric catalogue making.

The H. T. Paiste Co., Philadelphia, was represented by the genial secretary, Mr. E. A. Jenkins.

Locke High Voltage Insulators as well as other types of insulation made by the Locke Insulator Manufacturing Company, Victor, N. Y., were a prominent part of The Pettingill-Andrews exhibit.

Packard.—It goes without saying that the New York and Ohio Company and Packard lamps were ably represented all through the convention by Mr. W. D. Packard, who has missed only two conventions, and on one of these occasions he was abroad.

Mr. James G. Biddle, of Philadelphia, the well-known dealer in electrical and scientific instruments, took advantage of the convention to meet his many friends in the electrical fraternity.

Mr. Arthur L. Bosley, of The Electrical Material Company, Baltimore, was much in evidence.

The Crouse-Hinds Company, of Syracuse, was ably represented by Messrs. A. F. Hiller and C. Blanding as well as by Frank M. Hawkins, of New York, and S. S. Grady, of Boston. While no formal exhibit has been arranged for, a great deal of favorable comment was aroused by the models of the new Crouse-Hinds "Harpoon" guy anchors, which were shown in miniature, and by the literature which these gentlemen diligently distributed.

General Electric Company did not make an exhibit, although it occupied a large parlor and dispensed hospitality. On Friday a party of the delegates visited the General Electric shops at Lynn, Mass., where a great many interesting departments of the work are carried on. During the convention a paper was read on the new "magnetic" arc lamp, which was exhibited in the meeting room. Among the General Electric representatives present were Messrs. J. R. Lovejoy, E. E. Gilbert, W. C. Fish, C. D. Haskins, E. H. Mullin, C. B. Davis, H. W. Hillman, C. T. Moseman, G. T. Bridgman, J. R. Prentice, A. F. Giles, J. B. Pevear, E. D. Mullen, A. D. Babson, E. E. Peaseley, A. W. Ives, J. S. Butler, P. D. Wagoner, D. R. Bullen, H. L. Monroe, F. G. Vaughan, R. Fleming, F. M. Laxton, J. C. Kalisch, W. J. Hanley, J. Scribner, W. T. Wooley, H. L. Monroe, A. D. Page, G. F. Morrison, W. F. Willcox, T. E. Bibbins, H. H. Crowell, J. P. Felton, F. M. Kimball, S. B. Paine, R. B. Hampson, C. B. Burleigh, J. A. Wilson, H. W. Brown, O. F. Brastow, C. W. Fletcher, A. H. Coffin, M. J. Fitch.

J. G. White & Co. were represented by Mr. P. G. Gossler, lately general manager of the Montreal Light, Heat and Power Company, and Mr. H. J. Dowds, both of New York.

The Allis-Chalmers-Bullock interests were represented by Mr. Arthur Warren, manager of the Department of Publicity; Mr. G. H. Berg, manager of the Boston office of the Bullock Company; Mr. H. E. Rundlett, manager of the Boston office of the Allis-Chalmers Company; Mr. J. R. Jeffrey, assistant secretary of the Bullock Electric Manufacturing Co.; Mr. E. W. Goldsmith, manager of the Bullock offices in New York; Mr. E. T. Pardee and Mr. W. N. Ober, both of the Bullock Boston office. Handsome quarters were occupied on the parlor floor, and were filled with large photographs of notable plants and of machines built by the various interests. The rooms were filled at all times with delegates.

Stuart-Howland Company.—Among the most energetic and up-to-date firms in New England is the supply house of Stuart-Howland Company, Boston. They occupied handsome parlors at the Vendome and the neatness and care shown in their display was much commented upon. The staff were most assiduous in their attentions to all visitors, and were headed by Mr. G. M. Stuart. There were also in attendance A. H. Howland, A. E. Payne, C. R. Fish, Huntington Lee, C. B. Wetmore, James Wilson and W. Merrett. H. De Steese, of the railroad department, was also in attendance. The principal displays were Dale's wireless clusters, Helios arc lamps and Sterling incandescent lamps. Neat little souvenir whist counters were given away by this company.

Stanley Electric Manufacturing Company, Pittsfield, had their usual large corps to look after their interests. They occupied large quarters. The staff included Dr. F. A. C. Perrine and R. D. Lillibridge.

The Stanley Instrument Company, Great Barrington, Mass., had on exhibition a full line of their meters which had as exponents W. C. Andrews, S. O. Ochs, E. W. Gough, F. J. Alderson and F. W. Sanford.

McKenney & Waterbury, of Boston, showed a large line of fixtures and specialties through the attentions of W. A. McKenney, R. J. Green and N. I. Allen, Jr.

The Standard Vitrified Conduit Company, New York, had a fine exhibit and was looked after by the famous warrior, Capt. B. S. Barnard.

H. W. Johns-Manville Company showed a "raft" of their goods through the energetic efforts of Messrs. Joseph Sachs and J. Humphreys.

American Circular Loom Company had handsome parlors and gave out neat little souvenirs. Their representatives were everywhere and included Mr. A. T. Clark, R. B. Corey and Thomas H. Bibber. A face and figure much missed at this convention from this company were those of Mr. H. B. Kirkland, who was unavoidably absent.

The Pettingell-Andrews Company, Boston, exhibited in large and commodious parlors a large line of their various specialties. Their big force of representatives headed by Mr. C. B. Price included Messrs. F. S. Price, Keenan Palmer, Peterson, Johnson, Brokaw, White and Vanstagan.

Mr. George C. Ewing, of Boston, looked after the interests of the Cooper Hewitt lamp. He was also a very efficient member of the general entertainment committee.

The W. S. Hill Electric Company, of New Bedford, showed a complete line of their switches, switchboards and panelboards. Mr. C. S. Mendell was ever attentive to visitors and was ably assisted by Thomas N. White.

Mr. Harvey Hubbell, Bridgeport, exhibited some of his admirable specialties in charge of Mr. T. S. McLean.

Dale's Wireless Cluster was the subject of conversation wherever Mr. John H. Dale was and that was everywhere about the convention. His friends are legion, and he was in receipt of hearty congratulations on all sides on the immense success this new cluster is meeting with. Such specialties are a great boon to the art, and an incentive to the use of current by the consumer.

Simplex Electric Heating Company had a splendid exhibit of the various devices in this new art and was in charge of the veteran J. I. Ayer, who also read an excellent paper on the subject. It also had in attendance Messrs. A. W. Doe, C. W. Richards.

Mr. J. H. Mason had much to say for the merits of Simplex Electrical Company's wires and cables.

The Massachusetts Chemical Company occupied parlors in the Vendome and their interests carefully looked after by C. E. Farrington and L. O. Duclos. Mr. E. C. Green, president, also took a hand in.

The Holophane Glass Company, as usual made an excellent showing. They were represented by Mr. J. S. Codman, of Hale & Codman, Boston agents.

The Lundin Electric & Machine Company was represented by Emil C. Lundin, who is a veteran in the lighting field. The good points of his various specialties were carefully listened to and appreciated.

Chase-Shawmut Company were represented by H. P. Moore, sales manager, and F. D. Masterson.

The Condit Electrical Manufacturing Company, Boston, had Mr. S. B. Condit, Jr., and Fred W. Nason to talk the good features of the Elden circuit-breaker, and distribute quick-acting cutlery.

"Flexduct" was spoken for by Messrs. C. E. Corrigan and C. B. Roulet, of the Osburn Flexible Conduit Company.

C. F. Splitdorf found many interested listeners as to the merits of his new arc lamp cut-out.

Atlantic Insulated Wire & Cable Company were represented by Mr. G. F. Porter, now master of transportation, and invaluable from his long service and acquaintance as secretary of the Association.

Stone & Webster, Boston, were represented by D. P. Robinson, G. L. Tripp.

Albert & J. M. Anderson Co., of Boston, were represented by their president, Mr. Albert Anderson.

Holtzer-Cabot Company, of Brookline, Mass., were represented by President C. W. Holtzer, who took an active part in the proceedings.

National Electric Company, of Milwaukee, sent Mr. M. E. Baird to speak for its dynamos and motors, now becoming so widely known.

Electric Carriage Call Company made signals through Mortimer Norden and T. G. Bloomberg. It had an exhibit of much interest in its electric signs and calls.

Standard Chemical Company sent on G. B. Davis, president and manager.

Elliott Addressing Machine Company gave an admirable actual demonstration of what their machine could do. Mr. W. C. Mills, Boston manager, handled the exhibit with Mr. E. E. Mills, manager.

Phoenix Glass Company were fortunate to have present their veteran and popular manager, Mr. A. H. Patterson, with Mr. E. H. Peck as an affable "understudy." Mr. E. P. Elberts also helped them.

C. S. Knowles was represented by Messrs. C. H. Clark, Duncan Kennedy, G. Ober, G. S. Hutchins, J. Keefe, H. M. Saben.

Weston Electric Instrument Company had on hand their Boston manager, Mr. G. H. Moseman.

Mr. George Cutter, of Chicago, was a worthy and typical exponent of Western sentiment and progressiveness.

Buckeye Electric Company were represented by Mr. Le Roy P. Sawyer from the Cleveland office.

Bryan-Marsh Company had a good delegation in Guy V. Williams, J. P. Williams, D. W. Eyman, E. H. Houghton, G. C. Keech, S. E. Doane, F. W. Godfrey, W. C. Ballda. Converse D. Marsh was off somewhere regaling his cronies with Rabelaisian reminiscences; and draughting ads and other things.

"Okonite" delegation, like its trade mark, was twain. Its two halves, of course, were Willard L. Candee and G. T. Manson. These veterans have sometimes been seen apart, but not at a convention.

When the next Association amateur theatricals are given they are to play Damon and Pythias. They may be tempted to play the two Dromios.

NATIONAL CONDUIT & CABLE COMPANY had an excellent delegation in President George J. Jackson—"white"—and Messrs. W. S. Eckert, F. S. V. Sias, J. B. Honan, J. A. McQuale, Jr.

MR. F. W. LORD referred occasionally to the Lord Electric Company.

MR. C. O. BAKER was most unfortunately unable to attend, but the interests of Baker & Co., Inc., platinum, were well cared for by Mr. J. J. Lowthian.

ELECTRIC GAS LIGHTING COMPANY, of Boston, had an apparently ceaseless flow of representatives on tap. They "kept coming." Some of them answered to the names of W. F. Abely, K. L. Norris, F. H. Sherman, A. H. Boardman, C. H. Howes, C. E. Lee, S. A. Koltonsai,

AMERICAN DIESEL ENGINE COMPANY has no big American station yet like the Boston Edison, but Mr. Norman McCarty wept salt tears when he saw so much good money being wasted there on steam turbines. Sobs broke his utterance every time he spoke of it. And he had figures to prove it, too. With him was their assistant engineer, Mr. J. D. McPherson.

LOMBARD GOVERNOR COMPANY had a strong engineering delegation in Dr. Allan V. Garratt and Mr. R. B. Smith. With them was R. B. Stafford.

McINTOSH, SEYMOUR COMPANY were influentially represented by Messrs. J. A. Seymour from Auburn, N. Y., and by Mr. E. A. Merrill, of the New York office.

AMERICAN ELECTRICAL WORKS, of Providence, R. I., sent Mr. T. B. Baker from the Phillipsdale works and Mr. W. J. Watson from Gotham.

AMERICAN DISTRICT STEAM COMPANY, Lockport, N. Y., placed their interest in the hands of Messrs. C. R. Bishop and H. C. Eddy.

NATIONAL CARBON COMPANY were represented by Manager N. C. Cotabish from the Cleveland home circle and by Messrs. F. H. Murray, J. C. Irvine, J. F. Kerlin, F. C. Park, A. D. Spear.

MR. B. S. Barnard, the energetic president of the Standard Vitrified Conduit Company, got many a friendly handshake.

WAGNER ELECTRIC MANUFACTURING COMPANY were well represented by Messrs. Layman and Godfrey from out the West, as well as by Mr. B. Faxon, of their Boston office. They had a nice parlor on the first floor. Mr. John Mustard also greeted many old friends in his capacity as a Wagner man from Philadelphia.

ALBERGER CONDENSER COMPANY found their topic quite interesting to many central station men, and President L. R. Alberger and H. M. Montgomery were busy all the week getting in touch.

CROCKER-WHEELER ELECTRIC COMPANY, of Ampere, N. J., was represented by its president, Dr. S. S. Wheeler, and Secretary A. L. Doremus, and by R. N. C. Barnes, C. R. Metchear, A. J. Newell.

SHELBY ELECTRIC COMPANY, of Shelby, Ohio, was represented by Mr. C. W. Cartwright.

NERNST LAMP COMPANY found an efficient agent in Mr. George C. Ewing, who also proved a very competent and indefatigable local committeeman. He was aided by Mr. R. T. Vredenburgh, Mr. M. W. Hanks, Mr. E. R. Roberts, Mr. F. Gibbs.

SPRAGUE ELECTRIC COMPANY had present Messrs. H. G. Issertel, of its engineering staff, and Messrs. H. C. Farnsworth, A. Henderson.

GENERAL INCANDESCENT ARC LIGHT COMPANY sent Messrs. P. H. Klein, A. Foster, its Boston manager; F. Raymond, R. S. Hale, S. H. Blake.

MARSHALL SANDERS COMPANY was represented by Mr. Norman Marshall and C. A. Sanders.

H. S. POTTER ELECTRIC COMPANY were spoken for by the principal of that name.

MR. FRANK RIDLON needed no introductions to any central station man or supply man either. He was the Nestor of the convention, and fell easily into narrrtive, beginning "In the year one—." With him were E. W. Kellogg and N. L. Wood.

TRENTON PORCELAIN WORKS, with Messrs. George E. Maguire and Russell Howland, had the right blend of oratory and convincing "selling points."

WESTERN ELECTRIC COMPANY was one of the few Western houses making anything of an effort to be on hand. Mr. E. W. Rockafellow came up from New York to show that Chicago still remembers where the telephone started. With him was Mr. A. C. Morse.

DEARBORN DRUG & CHEMICAL COMPANY, of Chicago, were very adequately represented by Messrs. W. H. Edgar and W. B. McVicker.

FORT WAYNE ELECTRIC WORKS had a very handsome exhibit in one of the main ground floor parlors of all their well-known specialties in meters and other lines, while their famous little breeze circulators infused a grateful coolness into many a nook and corner of the room, the meeting hall, the committee rooms, and the hotel generally. The company was largely represented, its staff including Messrs. J. A. Smith, T. L. Sturgeon, J. C. Lott, F. S. Hunting, J. W. Hilgeman, J. Kent, A. A. Serva, J. O. Spear, Jr.

DOSSERT & Co., of New York, sent President J. J. Dossert and Secretary A. H. Willmont to safeguard their interests.

PRESIDENT B. C. KENYON, of the Diehl Manufacturing Company, was not able to arrive until the convention was in full swing, but he was not slow in "getting into the game" and helping to keep the ball in play. The company is extremely busy in all branches of its dynamo electric machinery.

CANADIAN GENERAL ELECTRIC COMPANY were represented by Mr. E. D. McCormack and Mr. A. B. Lambe. Young Mr. Nicholls was also present for himself and his father, Past President Frederic Nicholls, one of the best executives the Association ever had.

MR. RAY D. LILLIBRIDGE came during the week in behalf of the interests of his technical publication and advertising bureau, which has so large a patronage in the electrical and mechanical fields.

SUPPLY MEN were legion, as will be gathered from the items herewith as to exhibits and companies represented. The light and power art is throwing out its fibres and roots in various directions and bringing many industries within its scope. In addition to the concerns already noted, with the names of their sponsors, may be given the following, somewhat in order of registration: Federal Electric Company, W. H. McLain; Chicago Fuse & Wire Company, W. E. Weinsheimer, R. W. Smith; Manhattan Electrical Supply Company, J. W. McDonald; Bryant Electrical Company, F. V. Burton; Peerless Electric Company, A. Dunlop; De Laval Steam Turbine Company, C. Garrison; Benjamin Electric Manufacturing Company, B. G. Kodjbanoff; Safety Insulated Wire & Cable Company, F. B. Parsons; C. H. Whall & Co., F. R. Whall; Wheeler Reflector Company, H. C. Hawks; Munder Electric Company, C. F. Munder; Crescent Gas & Fixture Company, H. S. Beaman; Triumph Electric Company, C. A. Cotton; Kimmey Electric Company, C. A. Brown; Jandus Electric Company, E. L. Nash; Kinsman Electric Railway Supply Company, F. E. Kinsman; Ballou-Hutchins Electric Company, C. A. Ballou; Washington Carbon Company, J. S. Crider; Phillips Insulating Wire Company, A. N. Palmer; D. & W. Fuse Fuse Company, W. S. Sisson; R. D. Wood & Co., C. W. Lummis, H. G. H. Tarr; Re-New Lamp Company, G. H. Smith, H. Hastings; Tipless Lamp Company, R. S. Carrick; Crescent Insulating Company, L. F. Jackson; Magnet Wire Company, H. Hill; The Wire & Cable Company, E. F. Sise; Marion Insulated Wire & Rubber Company, J. L. Lucas; Fostoria Incandescent Lamp Company, H. S. Potter; Novelty Electric Company, C. E. Trump; Emerson Electric Manufacturing Company, E. L. Barkhouse; Electric Material Company, A. L. Bosley; Power & Mining Machinery Company, F. P. Thorp; Warren Arc Light Company, J. A. Stewart, I. P. Frink, Frank Stout; Sibley & Pitman, F. S. Gardner; Adams-Bagnall Electric Company, G. A. Thomson; Standard Varnish Works, J. C. Dolph; Lawrence Gas Fixture Company, C. V. Daiger; Buckeye Engine Company, A. K. Ashworth; E. B. Latham Company, E. B. Latham; National Wire Corporation, F. B. Parsons; Page Electric Company, J. P. Coghlin, F. S. Miller; New Britain Machine Company, R. S. Brown; Standard Electrical Manufacturing Company, J. P. Gilbert; Independent Incandescent Lamp Company, W. M. Rothschild; H. B. Camp Company, C. C. Baird; American Vitrified Conduit Company, S. A. Douglas; Wirt Electric Company, W. J. Thompson; Fred J. Lucey, of F. J. Lucey Co.; Sampson & Allen, A. T. Sampson; T. F. Carey Co., Thomas F. Carey, C. H. Currier; Hewes & Phillips Iron Works, Franklin Phillips; McMichal & Wildman Company, F. B. Wildman; Ansonia Brass & Copper Company, R. A. Cowles, F. H. Sherwood; Nightingale & Childs Co., E. G. Crosley; Charles A. Schieren & Co., G. H. Hamblett, E. A. Usina; National Biscuit Company, E. F. Cullen; American Steel & Wire Company, R. K. Sheppard, V. Goldthwaite, F. A. Keyes, A. F. Walker; Gillender & Son, Inc., W. Croft, Jr.; India Alkali Works, C. P. Powers; M. K. Kendall & Co., M. K. Kendall;

Packard Electric Company, Canada, G. C. Rough; White Automobile Company, T. H. Tucker; J. Wilkinson & Co., L. C. Billings; H. L. Slade; Bates & Neilson, J. Neilson; National Pipe Bending Company, W. G. Ruggles; M. W. Dunton Co., F. Chapman; Dwyer Machine Company, E. F. Dwyer; Potter & Earle, J. L. Potter; Heine Safety Boiler Company, E. L. McGregory; New England Machine Company, F. W. Smith; Macbeth-Evans Glass Company, E. S. Briggs, M. B. May; Gamewell Fire Alarm Telegraph Company, H. E. Stover; Falls River & Machine Company, G. A. Irving, E. J. Electric Insulating Company, M. H. Stearns; Colonial Electric Company, W. F. Curtis; W. Frederick Swift & Co.; J. H. Hallberg; Fields-Foulk Company, C. J. Fields; Standard Paint Company, L. G. Goodrich; Bryant Electrical Company, W. C. Bryant, F. V. Burton; American Brass & Copper Company, Randolph Osborn; Standard Optical Company, J. E. Bowker; Alphaduct Manufacturing Company, Russel Dart.

Habirshaw."—It was a great pleasure to see the interests of the India Rubber and Gutta Percha Insulating Company represented by the "good gray" Doctor himself. Besides Dr. W. M. Habirshaw, it sent Mr. J. B. Olson, the suave sales manager from New York.

Richmond Electric Company sent Mr. W. H. A. Davidson, who met many old electrical friends.

Mr. F. S. Terry, of the Sunbeam Incandescent Lamp Company, and the animating genius of the incandescent lamp pool was a late arrival, but none the less conspicuous. He was not allowed to lack opportunities for conversation. With him was Mr. B. G. Tremaine, the well-known manager, etc., of the Fostoria Incandescent Lamp Company.

Gould Storage Battery Company did not make an exhibit, but were energetically represented on the firing line by Dr. W. E. Winship and E. L. Draffen.

De La Vergne Machine Company were welcome strangers, and were able to send very acceptable representatives in George Richmond, Seward Babbitt and H. Borgstedt.

New York Insulated Wire Coompany referred to several big buildings in Boston as exhibits, and for other cities left its testimonials in the hands chiefly of Mr. James Wolff, of Chicago, and W. B. Fearing.

Swazey & Smith Co. were represented by H. W. Smith, T. Dun, G. H. Swazey.

CENTRAL STATION MEN.

The central stations of the country were more largely and widely represented than at any previous convention. Those registering were as follows:

Allegheny, Pa.—C. S. Mitchell, C. E. Warner.
Alliance, Ohio.—D. W. Law.
Altoona, Pa.—E. B. Greene.
Amesbury, Mass.—H. A. Sawyer..
Amherst, Mass.—D. Barry.
Asheville, N. C.—H. W. Plummer.
Atlanta, Ga.—T. J. Harper, A. L. Balsley.
Attleboro, Mass.—E. Fregoning, H. Daggett.
Auburn, Me.—H. T. Sands.
Auburn, N. Y.—J. S. Wise, Jr.
Augusta, Ga.—H. V. Schreiber.
Baltimore, Md.—J. F. Dusman, Douglass Burnett.
Bangor, Me.—J. W. Cartwright.
Bennington, Vt.—E. E. Larrabee.
Birmingham, Ala.—J. M. Bradley, R. Jemison.
Boise, Idaho.—D. Blanchard.
Boston, Mass.—C. L. Edgar, E. S. Mansfield, L. L. Elden, L. Vredenburgh, W. H. Atkins, L. M. Wallace, C. J. Hatch, G. V. Rowe, S. Hosmer, C. H. Parker, J. E. Larrett, F. S. Wilson, P. Winsor, C. D. Walker, A. S. Knight, C. H. Hodgkinson, A. H. W. Jaynes, I. E. Moultrop, S. J. Lent, E. H. Belden, W. D. Dyer, C. H. Ingalls, J. C. Redmond, W. P. Hancock, J. S. Vogler, D. Goss, A. C. Gray, G. P. Wisdom, H. P. Driver, C. R. Brown, W. Carrasco, A. G. Pierce, L. L. Edgar, J. W. Cowles, W. P. Fiske, W. H. Francis, G. Goettling, S. C. Clough, C. H. Herrick, W. W. Cummings, E. L. Caldwell, J. T. Boyd, W. T. Willey, W. C. Ross, G. B. Adams, W. E. Cook, H. F. Leavitt, F. Marshall, J. S. Cartwright, J. L. Bayle, E. B. Spike, T. F. Malone, G. W. Moses, F. B. Pitcher, F. V. Edgell, J. E. Elliott, W. H. Gardiner, Jr., W. J. Kennedy, P. Kent, R. E. Curtis, F. Brophy, F. D. Stiles, E. E. Phipps, W. H. Spaulding, F. Willis, C. F. Baker, G. S. Lawler, T. I. Donahue, H. E. Cutler, J. Y. Bradbury, B. Houghton, G. Attwood, E. J. Beugler, A. W. Friend, E. Mahler, A. E. Griffin, S. F. Lunt, W. C. Swan, H. F. Elden, F. G. Havlin, C. W. White, C. W. Enright, W. Minkler, W. E. Pierce.
Braintree, Mass.—W. P. Mercer.
Brattleboro, Vt.—L. C. White.
Brandon, Vt.—E. D. Blackwell.
Bridgeport, Conn.—W. T. Oviatt.
Bridgeton, Me.—C. A. Badwell.
Brockton, Mass.—P. Player, F. S. Pratt.
Brookline, Mass.—G. E. Crosby, J. A. Gould, J. W. Dodd.
Brunswick, Me.—A. C. Hopkins.
Buffalo, N. Y.—W. R. Huntley.
Burlington, Vt.—F. H. Parker.
Cambridge, Mass.—F. H. Raymond, R. A. Faye, W. R. Eaton.
Chicago, Ill.—L. A. Ferguson, W. M. Anthony, J. H. Gilchrist, R. L. Elliott, G. N. Eastman, W. L. Abbott, P. Junkersfeld.
Chelsea, Mass.—H. W. Moses.
Cincinnati, Ohio.—W. Von Phul.
Cleveland, Ohio.—S. Scovil, S. C. D. Johns, M. E. Turner.
Clinton, Mass.—R. R. Mackenzie.
Cohasset, Mass.—E. W. Bates.
Concord, Mass.—A. W. Lee, G. B. Lauder.
Connellsville, Pa.—L. Hill.
Denver, Colo.—I. Butterworth, H. L. Doherty, C. W. Humphrey, W. J. Barker.
Des Moines, Iowa.—F. L. Dame, R. H. MacMillan.
Detroit, Mich.—A. Dow, E. F. Phillips.
Dover, N. H.—T. Hawken.
Easton, Pa.—M. A. Maxwell.
Elmira, N. Y.—H. M. Beugler.
El Paso, Tex.—H. T. Edgar.
Evansville, Ind.—W. B. McDonald.
Fair Haven, Vt.—M. Patterson.
Fall River, Mass.—H. Bottomley.
Fitchburg, Mass.—W. F. Coggshall, A. H. Kimball.
Fort Collins, Colo.—G. B. Tripp.
Fulton County, Pa.—J. B. Klumpp.
Gardner, Mass.—H. H. Taylor, E. W. Furbush.
Glens Falls, N. Y.—B. E. Morrow.
Gloucester, Mass.—E. L. Munger.
Gloversville, N. Y.—J. C. De Long.
Greenville, Pa.—S. A. Gillespie.
Greenwich, Conn.—T. E. Fox.
Hartford, Conn.—A. C. Dunham, R. W. Rollins.
Holyoke, Mass.—A. W. Darby.
Hoosic Falls, N. Y.—R. D. Smith.
Hot Springs, Ark.—J. E. Cowles.
Houghton, Mich.—A. W. Leonard.
Hudson, Mass.—W. G. Lawrence.
Jackson, Mich.—W. P. Stephens.
Jamestown, N. Y.—F. W. Bullock, A. Weis.
Jersey City, N. J.—W. W. Titzell.
Joliet, Ill.—J. R. H. Staley.
Kenosha, Wis.—R. N. Kimball.
Kingston, N. Y.—F. Tobey, Jr.
Knoxville, Tenn.—L. H. Scherck.
Lockport, N. Y.—O. M. Diall.
Long Island City, N. Y.—J. N. Bissell.
Louisville, Ky.—A. M. Worthington.
Lowell, Mass.—N. T. Wilcox, D. Moore, J. J. Markham.
Lake Charles, La.—T. J. Bird.
Leavenworth, Kan.—A. S. Cook.
Lebanon, Pa.—F. C. Wright.
Leicester, Mass.—E. L. Watson.
Lewiston, Idaho.—E. H. Libby.
Lewiston, Pa.—E. F. McCabe.
Lexington, Ky.—T. Fitzgerald, Jr.
Lexington, Mass.—C. H. Miles.
Lima, Ohio.—J. A. Bendure, B. A. Conolly.
Lexington, Mass.—J. A. Sweetser.
Lynn, Mass.—C. F. Pritchard, W. P. Hazletine.
Madison, Wis.—R. D. Mershon.
Malden, Mass.—F. P. Royce, F. C. Sargent, A. E. Bliss.
Manchester, N. H.—J. B. Smith, S. P. Hunt.
Marion, Ind.—G. N. Tidd.

Marlboro, Mass.—C. B. Russell. H. E. Ryder, B. G. Scribner, A. A. Irish.
Marquette, Mich.—C. Retallic.
Mechanic Falls, Me.—H. A. Edgecomb.
Memphis, Tenn.—F. G. Proutt.
Meriden, Conn.—H. Minkwitz, C. A. Learned.
Middlebury, Vt.—C. C. Welles.
Milwaukee, Wis.—T. R. Mercein.
Minneapolis, Minn.—L. E. Eustis.
Montgomery, Ala.—H. C. Abell.
Montreal, Que.—R. M. Wilson, J. A. Burnett, W. McL. Walbank, R. S. Kelsch.
Morristown, N. J.—P. H. Lynch.
Mt. Vernon, N. Y.—J. T. Cowling.
Mystic, Conn.—T. C. Perkins, J. B. Smith.
Nantucket, Mass.—E. A. Chapel.
Nashville, Tenn.—J. P. W. Brown.
Nashua, N. H.—G. L. Sadler, P. T. Norton.
Newark, N. J.—J. J. Gaffney, H. D. King, D. Farrand, A. B. Carlton
New Britain, Conn.—L. S. Risley.
New Bedford, Mass.—G. R. Stetson, C. R. Price, F. H. Tabor.
Newburgh, N. Y.—E. J. Richards.
New London, Conn.—F. M. Tait.
Newton, Mass.—W. E. Holmes, W. H. Cole, W. A. Learned, C. K. Pierce.
New York City.—N. F. Brady, A. Williams, F. W. Smith, W. E. McCoy, J. D. Andrew, S. G. Rhodes.
New Haven, Conn.—A. F. Hunie.
Newport, R. I.—W. B. Gosling, M. W. Tenney.
Niagara Falls, N. Y.—J. E. Montague, G. W. Davenport.
Norristown, Pa.—D. A. Bertalette.
North Adams, Mass.—F. S. Richardson.
North Tonawanda, N. Y.—A. S. Allen.
North Abington, Mass.—F. N. Sanderson.
Nyack, N. Y.—S. R. Bradley, Jr.
Omaha, Neb.—H. A. Haldrege.
Oneida, N. Y.—C. W. Koiner.
Orange, N. J.—W. Partridge.
Ottawa, Ont.—J. Murphy.
Pawtucket, R. I.—J. A. Welch, A. Smith.
Peabody, Mass.—W. D. King.
Peoria, Ill.—R. S. Wallace.
Phoenixville, Pa.—J. W. Gillette.
Philadelphia, Pa.—J. B. McCall, W. C. L. Eglin, A. J. DeCamp, A. H. Manwaring, W. H. Johnson.
Pittsburg, Pa.—N. C. McPherson.
Pittsfield, Mass.—W. R. Gardener.
Plymouth, Mass.—E. P. Rowell.
Port Huron, Mich.—J. E. Davidson.
Portland, Me.—E. H. Mather, H. B. Chandler, C. A. Raymond.
Portsmouth, N. H.—J. S. Whitaver.
Poughkeepsie, N. Y.—T. R. Beal.
Providence, R. I.—W. I. Barnes, W. C. Woodward, A. B. Lisle, E. A. Barrows, W. S. Kelley, C. L. Smith.
Quebec, Can.—G. Hartmann.
Quincy, Mass.—F. W. Austin.
Reading, Mass.—S. S. Bell.
Renovo, Pa.—W. J. Murphy.
Revere, Mass.—A. B. Tenney.
Richmond, Va.—G. H. Whitfield.
Rockford, Ill.—M. A. Beal.
Rumford Falls, Me.—C. A. Mixer.
Rutland, Vt.—G. H. Haley.
Salem, Mass.—G. E. Teel, H. Kingsley, S. F. Smith, A. Morrill.
Sanford, Me.—W. E. Davis, W. J. Bodwell.
San Antonio, Tex.—H. H. Scott.
Sandy Hill, N. Y.—J. W. Wright.
Schenectady, N. Y.—E. F. Peck.
Silver City, N. M.—Wm. Merrill.
Sioux City, Iowa.—C. T. Gartland.
Skowhegan, Me.—C. J. Abbey.
Somerville, Mass.—F. E. Smith.
Southbridge, Mass.—A. F. Hall.
Suffield, Conn.—E. S. Goldthwaite.
Spokane, Wash.—R. Howes.
Springfield, Mass.—W. L. Mulligan, F. M. Fowler.
Steubenville, Pa.—S. P. Curtis.
St. Louis, Mo.—W. Gallagher, T. B. Carter, E. V. Matlack, O. M. Rau, W. F. White, Foster White.
St. Paul, Minn.—H. J. Gille, P. Doty.
St. Johnsbury, Vt.—E. E. Gage.
Syracuse, N. Y.—W. B. Ross, E. B. Doen.
Tampa, Fla.—B. R. T. Collins.
Terre Haute, Ind.—C. T. Mordock.
Thompsonville, Conn.—E. H. Farr.
Topeka, Kan.—C. R. Maunsell.
Toronto, Can.—H. G. Nicholls.
Trenton, N. J.—F. P. Lupke.
Utica, N. Y.—W. J. Brayton.
Washington, D. C.—L. E. Sinclair, E. S. Marlow.
Wallingford, Conn.—A. L. Pierce.
Waltham, Mass.—H. H. Kelly.
Waterbury, Conn.—D. B. Nish.
Waterville, Me.,—E. W. Crawford, R. J. Patterson.
Watertown, Mass.—O. W. Halladay.
Westboro, Mass.—G. L. Smith.
West Chester, Pa.—J. E. Pyle, Paul Spencer.
Williamsport, Pa.—E. H. Davis.
Winchendon, Mass.—F. W. Nourse.
Woodsville, N. H.—G. E. Mann.
Woonsocket, R. I.—F. S. Pond.
Worcester, Mass.—H. H. Fairbanks, W. H. Coughlin, F. H. Smith.

Death of William Wallace.—Every electric lighting man was grieved to learn during the convention of the death on Sunday last, in Washington, of Mr. William Wallace, who did so much pioneer work, for himself and with such men as Prof. Farmer to develop arc lamps, dynamos, carbons and other features of the industry. Many of the convention knew him and admired his fine personality.

Electrical World and Engineer

THE CONSOLIDATION OF "THE ELECTRICAL WORLD" AND "ELECTRICAL ENGINEER."

CONTENTS.

THE TELEPHONE INDUSTRY.

We present on another page some very interesting statistics, the first compiled in this country, with regard to the telephone industry, as regarded from the public service standpoint, and not including statistics of manufactures, given already in the Census of 1900. The work thus done now by the United States Bureau of the Census is of an extremely interesting and useful character, and these figures supplement admirably those which have already been presented with regard to street railways and central electric lighting plants. It will be seen that the telephone industry represents a capital of just over $450,000,000, covering slightly over 4,000 systems, with 2,315,297 telephones of all kinds, over which were exchanged during the year 1902 the extraordinary number of more than 5,000,000,000 telephone conversations. This industry employed 64,628 wage earners, to whom was paid $26,369,735, and 14,124 salaried officials and clerks, to whom was paid $9,885,886. The revenue derived from the industry reached the splendid total of $86,825,536, which is almost exactly the same as the sum returned for electric lighting central stations for 1902—certainly a striking coincidence—while it is also to be borne in mind that the capitalization of the electric lighting industry is very nearly the same as that of the telephone, being reported at the time mentioned as $504,000,000. The expenses for the year were $61,152,823. The interest on bonds was $3,411,948, and the dividends paid were $14,982,719. It would appear that, exclusive of the interest on bonds, the expenses were just about 70 per cent. of the income.

A very interesting feature of the report is that which shows up the extent to which rural telephony has grown and extended. The report includes 994 mutual systems, which are all of rural character, with 89,316 instruments, and 70,915 miles of single wire. In addition to these the commercial companies operate 15,598 rural lines with 138,426 miles of single wire and 121,905 telephones. Nor was this all, for the report included in addition 4,985 independent farmers' lines, with 49,965 miles of single wire and 55,747 instruments. These figures added to the others quoted above give a grand total for continental United States of 9,136 systems and lines; 4,900,451 miles of single wire, and 2,371,044 telephones.

One of the most interesting features also in connection with these statistics is the power which it gives us to make some kind of comparison between the Bell system as a whole, and that of the "independents" as a whole. Within the last year or two it has become the fashion in some circles to assert that the independent movement by its rapid growth had carried the statistics of independent exchanges so far as to leave those of the Bell exchanges utterly in the shade. The marked development of the independent system is beyond all controversy, but we have pointed out from time to time that the figures available did not altogether justify the claims put forward by some of the more enthusiastic independents as to the minority status into which the Bell system had been thrown. It would appear from the figures before us that the capitalization per telephone installation is about $195. It is generally conceded from the fact that the Bell system is largely centered in the cities, that the capitalization for the Bell installations would necessarily be heavier than for those in the independent networks. Yet even on the basis of $195 over the entire industry, and accepting the Bell stations at the end of 1902 as being only 1,277,983, it would appear that the Bell investment was the larger half. We should not be surprised if out of $452,000,000 aggregate it represented $300,000,000. The total revenue is placed at nearly [illegible] per [illegible] the Bell figures would represent at the [illegible] 1902 $64,000,000, [illegible] nearly 75 per cent.

The total of single wire for the whole industry is placed at 4,850,486 miles. The Bell system at the end of 1902 had slightly more than half this. The total number of telephone talks is given as slightly over 5,000,000,000 for the whole industry, while the figures for the Bell system for 1902 were given in the annual report of that year as 3,000,000,000. In fact, from whatever point of view the comparison may be made, the Bell system shows up in a favorable light, and must be regarded as holding its own. The increase in the investment in telephony is supposed to reach from fifty to seventy-five millions a year at the present time, but even on this basis the Bell system compares excellently, for the total amount added to construction and real estate by the companies in the system during 1903 was put down at $35,000,000, while in 1902, the year of the Census report, it is even said to have reached $37,000,000. One of the facts, however, that no census can bring out, but which we would all like to know, is, how much of the growth of the Bell system of late years is really attributable to the spur and stimulus of the competition engendered by the independent movement, which has undeniably been one of the most wonderful industrial "booms" of recent years, and one which has brought a maximum of benefit to the public with a minimum of drawbacks.

The Government and Wireless.

A newspaper dispatch announced some days ago that the President's Cabinet had directed the Navy Department to assume control of all wireless telegraph stations on the coast line of the United States and to operate them in the public service in connection with existing land wire systems. While the report has in rather vague terms been contradicted by Secretary Moody, the Chief of the Navy Bureau of Equipment appears to confirm it, and while disclaiming any intention to interfere with the present Marconi station on Cape Cod, gives as a reason for this exception that "The stations * * are for the general convenience and safety of the public, in a broad way supplementing the work of the Hydrographic office." If this means anything it would appear to indicate an intention to develop a coast line wireless service under naval control, which would involve, owing to the matter of interference, the prohibition of further stations operated by private enterprise. Such a policy cannot be too strongly condemned, not only because it involves an extension of military authority over what in times of peace is a purely commercial function, but because of the deadening effect on development of the art that would inevitably result from bureaucratic control.

That some government control over the location and operation of wireless stations is desirable cannot be denied, in view of the experiences with interference at yacht races between rival systems endeavoring to operate simultaneously in the same locality. Such control, however, would appear to come properly under the cognizance of one of the civilian departments of the government—the Department of Commerce, for example—and its details fixed after consultation with the various interests affected, rather than be assumed by a military department and exercised in the arbitrary manner inseparable from military control. Assuming the absence of present plans placing the coast line in a state to meet immediate war, under the suggested plan the wireless organization could very simply be transferred when actual war threatened, from the civilian to the military department. The Navy Department is particularly disqualified at the present time from becoming the custodian of wireless for the reason that in the past it has consistently turned a cold shoulder to American workers in the field. In the announcement of the Bureau Chief above referred to, the partisanship for the German system adopted by the navy—a system which owes its vogue in Germany not to merit but to the personal favor in which the inventor is held by the German Emperor—is displayed, and an entirely uncalled-for fling at the Marconi system indulged in. It would be gratifying if Secretary Moody's disclaimer could also be interpreted to cover the newspaper statements attributed to his subordinate.

Wave-Length Measurers.

The article by Dr. J. E. Ives appearing on page 1074 of this issue contains a number of interesting details and several novel features. Two oscillating circuits are commonly compared in periodic time by establishing an inductive relation between them (transformer fashion), whereby the oscillations produced in one might be aided to set up resonant sympathetic oscillation in the other. Under resonant conditions, the periodic times, or natural periods of the two circuits become equal, and, therefore, the wave lengths of the disturbances emitted by the two circuits become equal. In the ingenious apparatus described by Dr. Ives, the circuit to be tested is connected *conductively* to a small part of the excited circuit, so that a small voltage drop in the latter may be enabled to excite sympathetic resonance in the tested circuit. The connection between the two circuits is made at or near the neutral axis of the exciting circuit, or at the shank of the electric tuning fork, where the oscillation currents find a maximum or ventral segment, but where the oscillating voltage is zero, or finds a node. In this way the voltage brought to bear upon the tested circuit in resonance is only drop voltage due to current traversing reactance, or ix drop; and not the free voltage of the oscillating circuit.

As described in the article, the apparatus is a simple form of Hertzian oscillator, with symmetrical wings, or tuning fork limbs. Each limb has an adjustable Franklin pane capacity and an adjustable inductance. The two capacities are arranged to be matched or balanced. The two inductances are arranged to be symmetrical and to work together, so as to match. The resultant capacity may be varied in twelve steps from 200 abstatfarads up to about 22,500 abstatfarads. The inductance may be varied, by fine gradations, between about 3,600 abhenries and 5,800 abhenries. The wave length is always the circumference corresponding to the geometric mean of the abstatfarads and abhenries as radius; so that the apparatus can measure any wave length from $2\pi\sqrt{200 \times 3{,}600}$, or 5,340 cm. up to $2\pi\sqrt{22{,}500 \times 5{,}800}$, or 71,800 cm. Or, expressing the results in quarter wave lengths, and in feet, instead of in wave lengths and centimeters, the apparatus has a range of quarter wave measurement comprised between about 44 ft. and 590 ft. The quarter wave expression is convenient because it represents the mast height of unloaded wireless telegraph antenna having the wave length and frequency considered. It is a curious coincidence, by no means devoid of physical interpretation, that an abstatfarad is a centimeter in text-book lore, and an abhenry is also a centimeter in text-book phraseology. Consequently, the wave length of any oscillation circuit is the circumference of that circle whose radius is the geometrical mean of the electrostatic centimeters and magnetic centimeters. This is also an easily remembered rule.

The junction of the two wings of the Ives electric tuning fork is made through what appears to be a fairly massive brass rod of 20 mm^2 in cross-section. The resistance per centimeter of this rod may be one or two microhms, a quantity quite insignificant to produce an appreciable drop of pressure with any ordinary strength of current; but the inductance per centimeter may be, say, 3 abhenries, and at 3 million cycles per second, the mean frequency of oscillation of the apparatus (midway between the extremes produced of 417,500 and 5,620,000), the reactance per centimeter will be 56.5 millions of absohms, or over 1/20 of an ohm. A couple of feet of this brass rod would thus offer a reactance, or impedance, of about 3 ohms to such a frequency. With an oscillating current of even so feeble a strength as 100 virtual amperes, the voltage drop across two feet of the rod would be about 300 volts. This is quite a respectable voltage with which to attempt exciting an adjacent circuit into resonance, since, at resonance, such a circuit has no appreciable impedance beyond the omic resistance of its conducting parts.

The apparatus can, therefore, be brought into the neighborhood of a wireless telegraph antenna without sensibly disturbing the electromagnetic condition of the latter. The wireless antenna is then cut at the apparatus, and a few inches or feet of the brass rod are inserted in the gap. The capacity and inductance of the oscillator are then varied until the sympathetic frequency of the antenna is struck. The power of oscillating circuits in general, and of wireless telegraph antennæ in particular, as illustrated by the preceding numerical data, is very striking. We look at a 5,000-kw generator as a tremendously powerful machine. We then look up at the slender antenna running to the masthead of an ocean steamer, and are apt to consider the power of the apparatus as trivial because, forsooth, a few storage cells will operate it. The fact is, however, that the power of a wireless antenna is often of the same order as that of the 5-megawatt generator; only the generator keeps down to business and sustains the power steadily, while the antenna oscillates very powerfully for a microsecond or so, and then relapses into quiescence for a relative age.

HIGH VOLTAGE THREE-WIRE SYSTEMS.

Mr. Barnes' Convention paper, describing the 500-volt, three-wire lighting system at Providence, R. I., was received with much interest and aroused not a little profitable discussion. The use of high-voltage—that is, 200 to 250-volt lamps—has come to be somewhat common, particularly in isolated plants, but the development of the idea into a complete three-wire system is much out of the ordinary, and such a system, carrying as in this case more than 80,000 connected incandescent lamps besides motors and arcs, occupies a unique position among central stations. Obviously, the gain in copper by passing from the ordinary voltage for direct-current lighting distributions to 500 volts between the outside wires is very great indeed, and had it been practicable to secure it in the early days of the art it is safe to say that these high-voltage systems would have become common if, indeed, they had not displaced the low-voltage systems altogether. The alternating system came in, however, and crude though it was in the earlier stages of its development, it made plain the fact that economy of copper and wide radius of distribution could be obtained by it in a very simple and effective manner. The motor difficulty, however, remained for some time and not until the polyphase distributions were worked out was it possible to give good motor service with alternating currents. When, therefore, it became feasible to use a three-wire system with toward 500 volts across the outside wires, the field was already fairly well occupied by the polyphase systems.

The most serious consideration in the case of a high-voltage, three-wire system is the possibility of securing efficient and durable incandescent lamps, in the lack of which service must suffer and economy must fall. Five years ago when high-voltage lamps were relatively new they were very far from being satisfactory. The filament of such a lamp is necessarily very long and slender, and it cannot safely be driven so hard as a shorter and firmer filament. The early high-voltage lamps rarely did better than 4 watts per candle, and even at this figure their life was short. Of course, they could be made to do somewhat better in the larger sizes—24 to 32 cp—but these larger lamps have never been favorites in central station practice. At the present time, according to Mr. Barnes, the lamps in use of the Providence system average 3.3 watts per candle when new and have a satisfactory life before falling to 80 per cent. of the initial candle-power. We do not know how these lamps are treated in measurement, but if rated in the same way as lamps of half the voltage the performance is certainly very remarkable. Obviously, however, it is less good than can be obtained with lamps of lower voltage, which are also decidedly cheaper than high-voltage lamps, so that as against saving in copper must be charged up a steady loss of energy, or its equivalent in something else. In the case of alternating distribution, lamps of the highest class can be used and a still very much larger saving in copper can be secured, but at the cost of investment in transformers.

The arc lamp situation is far more serious than the incandescent problem. It is true that by adopting twin lamps the Providence company has been able to maintain an arc service, but of what quality? In the discussion which followed Mr. Barnes' paper, Mr. Woodward characterized the arc lamps as quite satisfactory, but it needs no argument to prove to any of our readers who have ever dealt with enclosed arcs that such an arc operated at 2.3 amp., whether singly or in pairs or groups, gives a light of singularly poor quality. The thin blue arc produced under such conditions is bad as light and most inefficient in production. We have grave doubts whether its efficiency in watts per candle-power is as high as that given by incandescents, and the color is nearly as objectionable as that from a mercury arc. So long as arc lights are a considerable item in central station practice, any distribution with a minimum voltage of about 250 at the customers' terminals is likely to be disadvantageous in this particular. In some cases arcs of large amperage grouped in series may help one over the difficulty, but broadly a high-voltage, three-wire system is at a very grave disadvantage in the arc lighting feature of the programme. On an alternating system at similar voltage one could fall back on Nernst lamps, but even this refuge seems to be denied at present to the direct-current distribution.

The motor service is easily handled on a high-voltage system, and we are disposed to think that fear of alternating motors has been the motive in installing the plant under consideration. It is well nigh impossible to persuade well-seasoned direct-current men—who even yet form an influential coterie—that first-class motor service can be given except by direct-current motors. Yet such is the case, as those familiar with polyphase motors well know. Even the variable speed problems, which are none too easy, can be solved by tact and skill. If the commutating alternating motor, such as is now being exploited for railway service, comes anywhere near meeting the hopes of its inventors, it will be at once available for stationary work. However this may be, the real or imaginary difficulties of alternating motor service are to-day no adequate reason for abandoning alternating distribution in favor of high-voltage three-wire working. Within a somewhat limited range of conditions the latter is unquestionably useful, but save in cases when the supply of energy is extraordinarily cheap, we do not see how it can equal a well-organized alternating system in economy. The mere fact that so high a voltage as 500 has to be used in interior work is serious from the standpoint of safety. Fixtures and accessories adequately safe can doubtless be secured, but either at higher cost than usual or with reduced factor of safety; and a voltage of 500, while not necessarily dangerous to life, cannot be trifled with. It would seem wise, therefore, to go slowly in adopting high voltage for the general work of interior wiring. It is perfectly true that high voltage sometimes gets upon the secondary wiring of an alternating system with disastrous results, but a well-grounded neutral desirable in every class of multiple-wire distribution is an effective safeguard in this particular. The future of electrical distribution depends on the development of new methods of lighting. With our present methods and apparatus, a 500-volt, three-wire system seems a questionable compromise.

Telephone Statistics of the United States.

Mr. W. M. Steuart, chief statistician of the Department of Manufactures in the Bureau of the Census, now part of the Department of Commerce and Labor, has just issued the following preliminary report on the telephone systems of the United States for the year ending December 31, 1902. This report, which is in line with those already issued in regard to street railways and the electric lighting industry, includes all commercial telephone plants, all mutual systems, and all separate "farmer" or rural lines in operation during any portion of the year. It does not include, however, any single lines of an exclusively private character. The inquiry is the first of the kind as to the telephone ever undertaken in this country, and has been extremely difficult on account of the rapidity of recent growth and the heterogeneous nature of the systems.

CONDENSED BALANCE SHEET.

	Total.	Commercial.	Mutual.
Total assets	$452,172,546	$449,485,693	$2,686,853
Construction and equipment (including real estate and telephones)	389,278,232	386,662,619	2,615,613
Stocks and bonds of other companies	9,938,342	9,938,342	....
Machinery, tools and supplies	9,689,691	9,657,956	31,735
Bills and accounts receivable	30,629,677	30,619,294	19,383
Cash and deposits	12,291,840	12,271,718	20,122
Sundries	344,764	344,764	....
Total liabilities	452,172,546	449,485,693	2,686,853
Capital stock	274,049,697	273,388,432	661,265
Bonds	73,981,361	73,978,361	3,000
Cash invested (unincor. systems)	6,161,299	4,571,318	1,589,981
Bills and accounts payable	44,491,066	44,411,639	79,427
Sundries	1,124,265	834,561	289,704
Net surplus and reserves	52,364,858	52,301,382	63,476
CONSTRUCTION, EQUIPMENT, ETC.			
Number of systems	4,151	3,157	994
Miles of single wire	4,350,486	4,779,571	70,915
Telephones of all kinds	2,315,297	2,225,981	89,316
Number of subscribers	2,137,256	2,048,736	88,520
Number of automatic pay stations	73,887	73,869	18
Number of all other pay stations	48,393	48,009	384
Farmer or rural lines owned by com. systems:			
Number of lines	15,598	15,598	....
Miles of single wire	138,426	138,426	....
Number of telephones	121,905	121,905	....
Number of party lines	258,166	(1)248,908	(2)9,258
Number of telephones on party lines	886,152	308,571	77,581
Number of public exchanges	10,361	9,419	942
Number of private branch exchanges	7,883	7,883	....
Manual switchboards, total number	10,842	9,901	941
Common battery system	837	830	7
Magneto system	10,005	9,071	934
Automatic switchboards	54	53	1
Mes. or talks during year, total No.	5,070,555,345	4,971,413,070	99,142,275
Local exchange	4,949,850,491	4,851,416,539	98,433,952
Long distance and toll	120,704,854	119,996,531	708,323
Employees and Wages:			
Salaried officials and clerks:			
Total number	14,124	13,958	166
Total salaries	$9,885,886	$9,871,596	$14,290
Wage-earners:			
Total average number	64,628	63,630	998
Total wages	$26,369,735	$26,206,065	$163,670
Revenue and Expenses:			
Total revenue	$86,825,536	$86,522,211	(3)$303,325
Total expenses (including taxes & fixed charges except int. on bonds)	61,152,823	60,871,002	281,821
Dividends paid	14,982,719	14,981,649	1,070
Interest on bonds	3,511,948	3,511,768	180
Net surplus	7,178,046	7,157,792	20,254

(1) Urban party lines.
(2) Rural party lines.
(3) Includes assessments.

In addition to the reports obtained from commercial and mutual telephone systems, shown in the above table, the bureau secured reports of 4,985 independent farmer or rural lines having 49,965 miles of single wire and 55,747 telephones. These figures added to the totals for the commercial and mutual systems give a grand total for the continental United States of 9,136 systems and lines, 4,900,451 miles of single wire and 2,371,044 telephones.

A number of commercial systems operate in rural districts, but combining the totals for farmer or rural lines owned by commercial systems, mutual systems and independent farmer or rural lines gives a total of 21,577 systems and lines, 259,306 miles of single wire and 266,968 telephones, operated exclusively in rural districts.

In addition to the statistics presented above for the continental United States, reports were received for one commercial system in Alaska and seven in Hawaii, having a total of 4,732 miles of single wire, 2,493 telephones of all kinds, 3,461,000 messages or talks during the year, $112,068 total revenue, $76,307 total expenses (including taxes and fixed charges), and $25,858 paid in dividends, leaving a net surplus of $9,903.

The final report will contain an analysis of the above totals and present detailed statistics by States and for other phases of the industry. This report will be in the nature of a full discussion of the subject, in the manner of the reports that have been prepared nad are also to be published in regard to electric lighting, street railways and electric manufacturing hen these are all finished the electrical industries of the United States will have received a thorough treatment of the kind, and will have been reviewed so as to present a permanent record of the state of the art and its industries at the beginning of the century. This information, therefore, in addition to its present value, will constitute a basis of comparison for all time.

Programme of International Electrical Congress.

Below is the preliminary programme for Sections B and C of the International Electrical Congress. The programme of Section A has already been published and that of the other five sections will shortly be given out:

SECTION B—GENERAL APPLICATIONS.

Chairman, Prof. C. P. Steinmetz; secretary, Prof. Samuel Sheldon.

Name of Author.	*Title of Paper.*
Prof. E. Arnold,	Direct-Current Commutation.
Dr. O. S. Bragstad,	Compensated Alternators.
Col. R. E. Crompton,	Standardization of Dynamo-Electric Machinery and Apparatus.
M. Andre Blondel,	Calcul des Alternateurs.
Profs. Drs. Elster and Geitel,	Uber die Naturliche Radioactivität der Atmosphare und des Erdbodens.
Prof. Dr. Clarence P. Feldmann,	The Distribution of Voltage and Current in Closed Conducting Networks.
M. A. Heyland,	Self-Regulating and Compounded Synchronous Machines.
W. M. Mordey,	To be announced.
A. Nodon,	Rectifiers.
Sir W. H. Preece,	Electricity in Ancient Egypt.
Prof. C. A. Adams,	Magnetic Leakage in Alternating-Current Machinery.
Mr. C. Day,	Electric Motors in Shop Service.
Mr. J. W. Esterline,	Carrying Capacity of Cables and Conductors.
Mr. H. W. Fisher,	Sparking Distances Corresponding to Different Voltages.
Prof. H. J. Ryan,	The Design of Insulators.
Mr. D. B. Rushmore,	The Regulation of Alternators.
Prof. E. B. Rosa,	The Influence of Wave Shape upon Alternating-Current Meter Indications.
Dr. Clayton H. Sharp,	The Equipment of a Commercial Testing Laboratory.
Prof. H. B. Smith,	Very High Voltage Transformers.

SECTION C—ELECTROCHEMISTRY.

Chairman, Prof. H. S. Carhart; secretary, Mr. Carl Hering.

Prof. Dr. S. Arrhenius,	Methods of Determining the Degree of Dissociation.
Geh. Reg. Prof. Dr. W. Borchers,	Electrometallurgy of Nickel.
Sherard O. Cowper-Coles,	Electrolytic Methods for the Rapid Production of Copper Sheets and Tubes.
Dr. F. Dolezalek,	Subject to be announced.
J. Sigfried Edstron,	Electrical Extraction of Nitrogen from the Air.
Dr. H. Goldschmidt.	Alumino-Thermics.
Prof. Dr. F. Haber,	Electrolytische Zerstörungen in der Erde.
Dr. P. C. L. Heroult,	Electrometallurgy of Iron and Steel.
Mr. J. Swinburne,	Chlorine Smelting.
Prof. W. D. Bancroft,	The Chemistry of Electroplating.
Mr. A. G. Betts and Dr. Edward Kern,	The Lead Voltameter.
Prof. H. S. Carhart and Dr. C. A. Hulett,	The Preparation of Materials for Standard Cells.
Thos. A. Edison,	Alkaline Batteries.
Dr. K. E. Guthe,	The Silver Voltameter.
Mr. Carl Hering,	The Units Employed in Electrochemistry.
Mr. J. T. Morrow,	Notes on Electrolytic Copper Refining.
Prof. J. W. Richards,	The Energy Absorbed in Electrolysis.
Prof. T. W. Richards,	The Relation of the Theory of Compressible Atoms to Electrochemistry.

The Largest Electric Water Power Plant in New Hampshire.—II.

Hydraulic power can seldom be developed while the dam intended to maintain the head of water is in detached sections, the canal that conveys the water is incomplete, and the greater part of the electric station to be operated by the water remains unbuilt; but this is being done at Garvin's Falls, N. H. These conditions were made possible by the old dam 700 ft. up stream from the site of the new, by the upper section of the old canal that brings water from one end of the old dam to the head gates of the new canal, and by the fact that one-third of the electric station was completed some months before the other two-thirds were begun.

FIG. 1.—TAIL RACE, GARVIN'S FALLS.

After it was decided to replace the old dam 1,240 ft. up stream from the incomplete electric station, by a new dam some 700 ft. down stream, to replace the lower section of the old canal by a new one of much greater section 500 ft. long, and to extend the electric station, the problem was to discontinue the use of the electrical equipments already installed during the shortest time possible.

This problem was solved by deepening the tail race below the electric station, building the 500 ft. of new canal and extending the forebay wall and station foundations between June 5, 1903, when the contract for the work was signed and November of the same year, when water from the upper section of the old canal was let into the new.

The old canal is unable to bring down the entire flow of the Merrimac River from the old dam even in the summer season, and a coffer dam was, therefore, built a little above the site of the new masonry dam to lay bare a part of the river bed. This coffer dam for the greater part of its length, including that next to the right bank of the river, is built with bags of sand that were transported to their positions by wheelbarrows. Heavy rocks and earth make up the coffer dam in that part nearest the left bank of the river, and a break spanned by a wooden bridge remains open between the end of the coffer dam and this bank for the water that cannot pass down the canal. In this way the water flowing over the old dam was forced to the lowest part of the old channel, while sections of the new dam were built in other parts. The site selected for the new dam was particularly favorable because it afforded a foundation of bed rock all the way across the river with comparatively little excavation. Surface seams in the bed rock on the dam site were filled with mortar, and all loose parts were removed by barring so as to leave a clean surface for the mortar in which the masonry was laid, thereby making a water-tight joint. Any springs flowing up through seams in the ledge were grouted and piped.

Along the entire length of both the high and low-crest sections, the dam, it is set into a trench cut for its entire width in the river ledge. The bottom of this trench is divided into two parts by a projection of the ledge parallel to the length of the dam, and the lower part is that beneath the heel. For the low-crest section of the dam the approximate width of the trench in the bed rock is 31 ft., and the width of the deeper part of the trench, that beneath the heel of the dam, is about 8 ft. In depth the trench varies somewhat with the solidity of the ledge, but the approximate figures are 6.5 ft. at the heel and 4 ft. at the toe of the dam in its low-crest section. The projection of the bed rock in front of the heel of this part of the dam is about 4 ft.

In height the low-crest part of the dam is about 25 ft. above the bottom of the trench at the heel, and 18.5 ft. above the surface of the bed rock outside of the trench. The top of this low-crest section of the dam is at the same elevation as the top of the old dam that is 700 ft. up stream. This equality of elevations will prevent the loss of any flowage rights on the one hand, or any land damages on the other, after the old dam is removed. The great width compared with height in this dam is designed to provide stability against the high freshets to which the Merrimac River is subject. During the highest freshet on record the river at Garvin's Falls reached an elevation of 9.7 ft. above that of the low-crest section of the new dam, on March 2, 1896. The low-crest section of this dam as now constructed has a pressure line that just coincides with the down stream side of its middle third at an elevation 20 ft. below the crest, when the water over this crest is 20 ft. deep. Toe stones in this section of the dam have an elevation 16 ft. below the crest at their upper outside corners, and each of these stones stands about 2 ft. above and extends about 1.5 ft. below the natural ledge beyond the toe. On the up stream side of the dam the batter is 5 to 1, and the space between this batter surface and the side of the trench is filled with concrete. Between the top corner of the toe stones and the natural ledge to a distance of some feet down stream there is a sloping layer of concrete.

At the top corner on the up stream side of the dam the surface to the crest line is curved with a 10-ft. radius. Then comes a horizontal surface 1 ft. wide and tangent to this another surface with a 10-ft. radius turns the down stream corner of the crest. Next is a slope of 5 to 3 for a distance of 7.34 ft., and then comes a concave surface of 10-ft. radius that extends to within 1 ft. of the toe line. This last foot of surface on the down stream side of the dam is horizontal.

Of the total dam length of about 550 ft. between abutments, 75 ft. is taken up by the high-crest section, which juts out into the river from the left bank. The crest elevation of this section is 2 ft. above that of the low crest, and the height of this section above the bed rock is as little as 10 ft. in some parts. This high section of the dam, like the lower one, sets in a trench cut through the bed rock of the river. In width the trench is 8 ft. under the heel, and 22 ft. from heel to toe of the dam. On the up stream side the depth of the trench is 6 ft., on the down stream side 4 ft., and the ledge projection against the down stream side of the heel is approximately 3.5 ft. high. From heel to crest this section of the dam measures as much as 18.5 ft. On the up stream face of the dam the batter is 5 to 1, and on the down stream face it is 5 to 3. In this

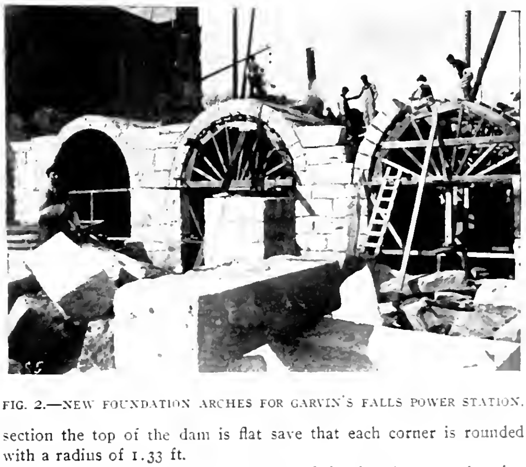

FIG. 2.—NEW FOUNDATION ARCHES FOR GARVIN'S FALLS POWER STATION.

section the top of the dam is flat save that each corner is rounded with a radius of 1.33 ft.

At the toe of this section the stones of the dam have an elevation about 1 ft. above that of the bed rock just beyond, and a layer of concrete with a sloping surface is used next to the toe.

Each capstone on the crest of the dam along the up stream side, which is cut to shape on its two exposed sides, is not less than 4 ft. square and 2.5 ft. thick, and is secured to the two courses next underneath by 4-ft. long dowels. All the other capstones are also cut to dimensions and are not less than 4 ft. long lengthwise of the crest, and 2.5 ft. deep. The down stream face of the dam as well as the crest is composed of ashlar masonry in both sections, but the up-stream face of the dam below [illegible] and also its core is of rubble masonry. The two faces of the dam and also its crest are laid with mortar composed of one part of Portland cement to two parts of sand, and the hearting of the dam is laid with mortar of one part Portland cement to 2.5 parts of sand. Every stone in the dam was required to be laid in a bed of mortar, and no grouting was permitted. In the heart of the dam various sizes of stone were used and regular coursing was avoided so as to obtain good vertical as well as horizontal bonding. For the rubble on the up stream face of the dam every third stone in each course was required to be of headers, and this is also true for the ashlar masonry on the down stream face.

The length of headers in the down stream face is not less than 4 ft., and the length of stretches not less than 2 ft., in a direction normal to the face. The rise of courses is between 18 and 24 in., the minimum face length of stretchers is not less than 3 ft. and that of headers 2 ft. On the down stream face of the dam the width of joints to a depth of 3 in. is ½ in., and in the entire depth of joints the width is not more than 1½ in. Along the entire crest of the dam and for several courses above the toe of the overflow section, the adjoining stones of different courses are secured to each other by dogs. Toe stones in this section are very heavy and have cross-sections about 4 ft. square in plains normal to the face of the dam. All dowels, dogs, clamps and flashboard pins were made of 1¼-in. round wrought iron galvanized, and the dogs were galvanized after bending.

No masonry or concrete in any part of the work was allowed to come in contact with water until it had been in position at least 24 hours. Work in laying masonry in the dam was permitted when the temperature was as low as 22° F., on condition that the materials for the mortar were heated and that salt was mixed with them. All cement used in the dam, canal and power house was of the Portland variety and equal to the best American manufacture. Granite was the only stone used in the dam and other masonry.

The left bank abutment consists of a concrete core wall that extends several rods up into the bank, a cross wall at its river end, and two wing walls for this cross wall. Like all other parts of the dam this core wall is based on bed rock, and its cross-section is tapering, being about 8 ft. wide at the bottom and 3 ft. at the top, with a height not far from 20 ft. Concrete for the core wall was mixed with one part Portland cement, 2½ parts sand and 4½ parts broken stone. Cross and wing walls at the river end of the core wall were built of rubble masonry and ashlar facing. Between the core walls and the wing walls the spaces were filled with layers of earth and small stones thoroughly rolled or rammed.

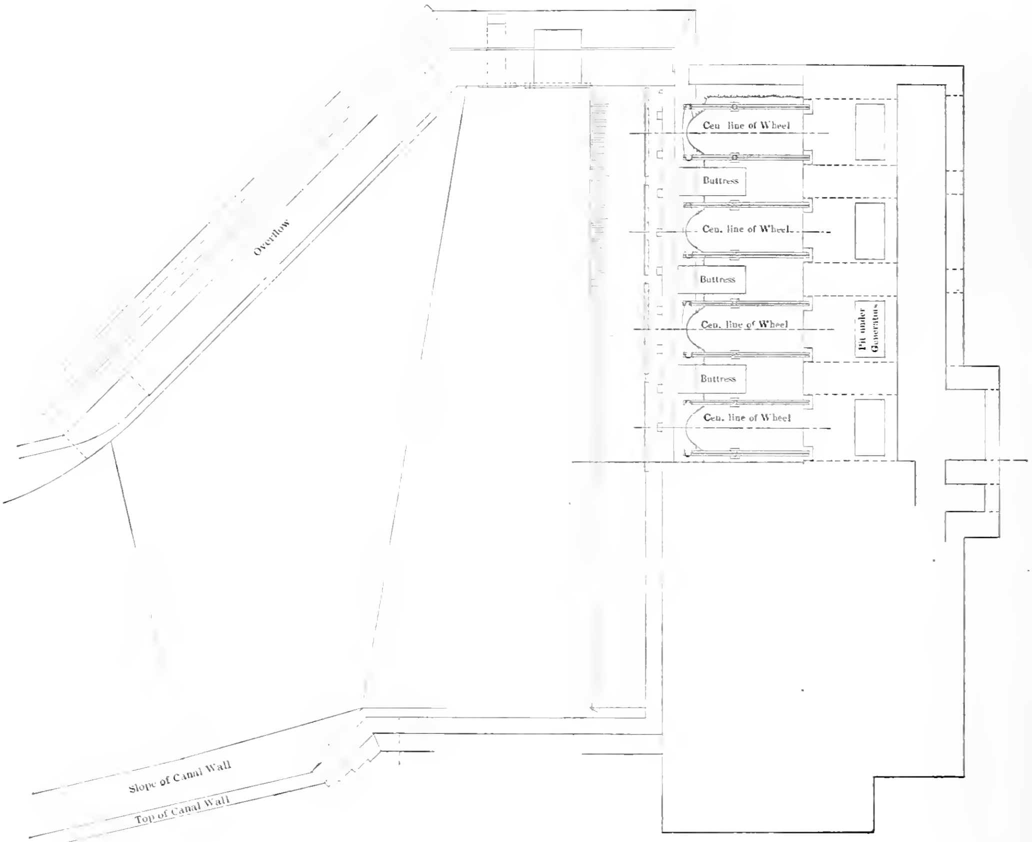

FIG. 3.—PLAN OF FOUNDATION AND FOREBAY WALLS, GARVIN'S FALLS, N. H.

The right bank abutment consists of a cross wall, a wing wall about 60 ft. long on the down stream side, and a wing wall about 139 ft. long on the up stream side. In the length of the down stream wing wall 47.5 ft. forms an overflow section on the river side of the new canal. This overflow section has an elevation 3 ft. greater than that of the low-crest portion of the dam, and 1 ft. greater than that of the high-crest section. At the ends of this overflow section on the wing wall the elevation is that of the main portions of the canal walls or 5 ft. tbove the low crest of the dam. On its river side this overflow section has a batter of 4 in. per foot. In its central portion the cross wall of this abutment has its top 5 ft. above the low crest of the dam. The site of both wing walls at the right bank abutment was a natural ledge that formed the river bank, and this ledge was higher than the present top of the down stream wing wall so that a large amount of rock excavation was necessary both in the bed of the canal and at the site of the wing. Where the cross wall joins the down stream wing a large section of the natural ledge was left to bind the corners together. Rubble stone masonry faced with ashlar on the river side of the overflow section was used in the down stream wing wall.

The cross wall was built of rubble concrete masonry, and this type of masonry was also used in the up stream wing wall, which is also the head gate wall; above an elevation 5 ft. higher than the low crest of the dam. Rubble concrete for this purpose was mixed with one part Portland cement, 2.5 parts sand and 4.5 parts stone or gravel. No stone of large area in this concrete was allowed within 10 in. of the outside surfaces of the work. Below an elevation 5 ft. above the low crest of the dam the head gate wall is formed of concrete mixed with one part Portland cement, 2.5 parts sand and 4.5 parts stone or gravel graded up to not more than 2 in. in its greatest dimension.

FIG. 4.—UPPER END OF CANAL, GARVIN'S FALLS.

Entrance to the new canal is closed by 95 ft. in the length of the head gate wall, and the remaining 44 ft. of its length forms a wing that runs up into the bank. From the end of this wing a concrete core wall crosses the right of way occupied by the express tracks of the Boston & Maine Railroad which borders the canal. Along its top the elevation of the head gate wall is 15 ft. above that of the low-crest dam, and the width at the base is 30 ft. in that part of the wall that contains the head gates. At its top the width of this wall is 8 ft., its up stream face is vertical and on its down stream face the batter is 4 in. per foot down to a level 12 ft. below the top, where the abutments begin. The base of the wall is pierced by six archways leading from the river into the canal, each of these archways being 10 ft. wide and 15 ft. high. The floor level of these archways corresponds with that of the canal adjoining them, and is 12 ft. below the low-crest portion of the dam. From the floor of the archways to the top of the head gate wall above them the distance is 27 ft. The sill outside of the arches on the river side of the forebay wall is 3 ft. below the arch floors. On its canal side the length of the head gate wall is 90 ft., and the center line of the wall makes an angle of approximately 56° with the center line of the canal. It is consequently necessary for water entering the canal through the head gate arches to change its direction of flow by 34° before passing down the canal.

This change in the direction of water entering the canal begins just inside of the head gate wall, and is effected by a section of the canal wall toward which the flow through the head gate wall is directed. In this section the canal wall is formed of concrete 4 ft. wide at its top and 5 ft. at the thickest part of its base. Natural ledge in which this part of the canal is excavated forms both the foundation and the backing for this concrete section of the canal wall. The entire canal wall between the head gates and the forebay has a top elevation 5 ft. greater than that of the low-crest dam, save in the overflow section already mentioned. Just inside of the head gate wall the elevation of the canal bottom is 12 ft. less than that on the low crest of the dam, and there is a gradual fall in the bottom of the canal so that at the line where it widens into the forebay the elevation is 13 ft. below the overflow portion of the dam. From this it may be seen that the general height of the canal wall is 17 to 18 ft. above the canal bottom. Along almost its entire length of 500 ft. the canal was excavated either wholly or partly in rock, and much of the sides consists of the natural rock surface. At some points such surfaces had large seams and these were dug out and filled with concrete. Along the greater part of the canal the walls were laid with dry rubble masonry, either from the bottom up, where the cut was in earth, or above the top of the natural ledge, where the cut was in rock. These rubble side walls are laid with a slope of 6 in. per foot of height, and is 3 ft. thick. At a distance of about 113 ft. from the down stream face of the head gate wall along the center line of the canal the bottom width shrinks to 62 ft., the width at the elevation of the low crest of the dam to 74 ft., and the width on a level with the tops of its side walls to 79 ft.

The canal holds these widths to a point on its center line that is distant about 144 ft. from the canal side of the end wall of the forebay, and then begins to widen. At the face of this end wall the top width of the forebay is 134.5 ft. Near that cross-section where the canal begins to widen into the forebay the bottom takes on a slope that carries it from an elevation that is 13 ft. below the crest on the river section of the dam down to 17 ft. below that crest, along a line that is 60 ft. at one end and 37 ft. at the other from the inner face of the head forebay wall. Between this line and the head wall the bottom of the canal is level. On the river side of the forebay there is an overflow section 90 ft. long and with its top 2 ft. higher than the low crest of the dam. This overflow section is 8 ft. wide on top, about 19 ft. wide at its base, is 15 ft. high above the natural ledge on which it stands, and is built of rubble stone masonry laid in cement mortar. Between the down stream end of this overflow section and the head wall of the forebay, there is a stretch of wall 40 ft. long on the river side that contains openings for the flush and waste gates. The waste gate opening is 4 ft. wide, of about the same height, and has its bottom approximately on a level with the forebay floor at that point. The opening for the waste gate is 10 ft. wide, has its bottom 10 ft. above the forebay floor and 7 ft. beneath the low-crest level of the dam, and extends to the top of the wall in which it is located, 5 ft. above the low crest of the dam.

Rubble stone masonry laid in cement mortar forms the head wall of the forebay, and this wall serves also as one side of the wheel room in the power station. On top the elevation of this wall is 8.5 ft. greater than that of the low crest of the dam, and its base runs down to a plain 20 ft. below that crest. At its top the thickness of this wall is 3.5 ft., at the low-crest level of the dam, and the flow at line of the canal the thickness is 7 ft., and at the level of the forebay floor the thickness is 10.5 ft. This wall is further strengthened by buttresses that extend into the wheel room between the wheel cases.

FIG. 5.—HEAD GATES, GARVIN'S FALLS.

On its forebay side the head wall of the forebay is vertical and in front of this wall is the steel rack 134.5 ft. long and 20 ft. in vertical height, reaching from the bottom of the forebay to a line 3.5 ft. above the low crest of the dam. The face of this rack is 11 ft. 10⅜ in. from the face of the head wall at the bottom, and 6 ft. 10⅞ in. at the top. In structure the rack is built up with 15-in., 42-pound steel I-beams reaching from top to bottom and spaced with centers 10 ft. 6 in. apart. At their lower ends these 15-in. beams are riveted to a 20-in., 60-pound horizontal I-beam, and at their tops to a 15-in., 42-pound I-beam, while three other horizontal beams tie those running up and down the rack together at intermediate points. The horizontal 20-in. I-beam at the bottom of the rack is set in a bed of concrete and bolted to the natural ledge beneath. At the top each I-beam running up and down is secured to the forebay wall by an 8-in., 25-pound beam, and at 8.5 ft. from its lower end an I-beam of 10 in. and 40 pounds weight serves a like purpose.

The face of the rack is made up of wrought-iron bars set edgewise, each bar being 3.5 in. wide and ¼ in. thick. Bars are held together by round rods of ⅜ in. diameter that pass through them, and the spaces 1¼ in. wide between bars are obtained by placing a length of standard ⅜-in. iron pipe 1¼ in. long on each rod between each pair of the ¼ by 3.5-in. bars. The face of the rack is divided horizontally into upper and lower sections. In the upper section each of the ¼ by 3.5-in. iron bars is 12 ft. ⅝ in. long and is held in position by four of the ⅜-in. round rods. In the upper section each of the ¼ by 3.5-in. bars is 8 ft. 5¾ in. long and is held in position by three of the ⅜-in. round rods. Vertically the face of the rack was made up of sections most of which were 3.5 ft. wide each.

Beyond the head wall of the forebay and its buttresses the natural ledge beneath the power station was excavated to an elevation 33 to 35 ft. beneath the low crest of the dam, and 16 to 18 ft. below the floor of the forebay. This depth of excavation provided room for the foundations and the escape of the tail water, and permitted an ordinary depth of tail water of at least 5 ft. On a line about 20 ft. beyond the vertical face of the natural ledge that forms the foundation of the main portion of the head wall of the forebay, and about 10 ft. beyond the ledge projections that support the buttresses, the arches underneath the generator room of the power station begin. These arches, seven in number, form a continuous row from one end of the power station nearly to the other, and the length of each arched opening in this row is 20 ft. Between the up stream face of this row of arches and the foundation of the forebay wall there is no masonry, and the space is spanned by steel I-beams each 27 ft. long that are supported at one end by the head wall of the forebay, and at the other end by the arches just named.

FIG. 5.—BUILDING THE DAM, GARVIN'S FALLS.

These I-beams are placed in pairs close together, and from center to center each pair is distant about 11 ft. from the next. Two pairs of these I-beams serve to support each wheel case and the draft tubes from the wheel cases drop down between the beams to the tail water below. In the line of arches above mentioned each of the six main archways through which the tail water from the large wheels passes is 14 ft. wide and 16 ft. high above the bed rock floor. Between the archways the walls are 7 ft. thick, and the top of the arch masonry is 16 ft. lower than the crest of the dam. Between the down stream side of this row of large arches and another row of arches that makes up the foundation for the down stream wall of the power station there is an open space nearly as long as the station and 10.25 ft. wide for most of its length. This space is spanned by steel beams and above these beams and the row of arches already described comes the floor of the generator room at an elevation 15 ft. beneath the low crest of the dam, and 13 ft. above the ordinary tail water level. The arched wall that supports the down stream wall of the station is 4 ft thick and contains seven archways which are respectively opposite to the seven archways beneath the floor of the generator room.

All of this arch work beneath the station is of rubble stone masonry laid in cement mortar, and rests on the natural bed rock. Just outside of the arches under the down stream wall of the station the bottom of the tail race has an elevation 33 ft. less than that at the low crest of the dam, and there is a little slope from this point to the river a few rods distant. The wall of the tail race is dry rubble masonry. To provide for the increased flow of water, the lower end of the tail race was deepened while the extension of the station foundations was in progress.

The kindness of Hollis French and Allen Hubbard, of Boston, the engineers of all the above work, has made it possible to give these structural details of the largest electric water power plant in the State of New Hampshire.

On a New Standard of Wave-length.

By Dr. James E. Ives.

In a recent number of the Electrical World and Engineer (February 6, 1904), I have given the results of some measurements of the wave-length of free vibrations in antennæ and closed oscillating circuits. I now propose to describe the *standard of wave length* with which these measurements were made.

This instrument was designed for the American De Forest Wireless Telegraph Company, conjointly by Dr. Lee de Forest and the author. Its general appearance is shown in Fig. 1. It stands 22 in. high, is 30 in. wide and 14½ in. deep. It is symmetrical in form, consisting of two variable condensers, and two variable inductances similarly placed on each side of a spark-gap. The condensers are made of sheets of glass covered with tin-foil, and placed in the base of the instrument. Each of the inductances consists of two concentric circles of wire supported by hard-rubber rings, the outer rings being fixed in a common vertical plane, and the inner, rotating together about a horizontal diameter. The circles and all connecting wires are made of No. 10 bare copper wire (.102 in. in diameter).

Starting at the spark-gap and tracing the connections on the right-hand side, we see that a wire leads to the right-hand condenser; from the condenser a wire passes to the outer circle of the right-hand inductance; from the outer circle we pass by means of a sliding contact to the inner circle, and from the inner circle by means of another sliding contact to a wire that goes to the *contact bar* at the top of the instrument. The contact bar is a brass rod of rectangular cross-section, which, as will be seen from Fig. 1, is bent upon itself. The dimensions of its cross-section are ¼ by ⅛ in.

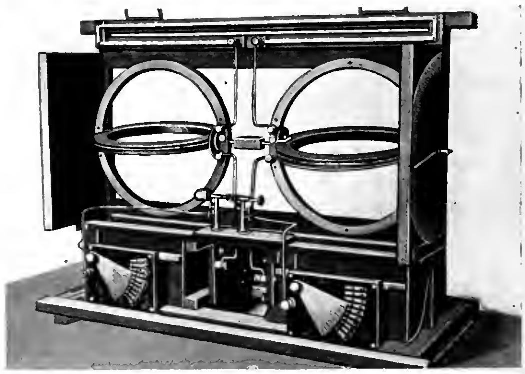

FIG. 1.—VIEW OF INSTRUMENT.

The outer circles of wire are 11¼ in. in diameter, and the inner circles 9⅝ in. The sliding contacts are made by means of two small concentric flat brass rings, which are attached to the inner hard-rubber ring, making contact with two small brushes fastened to the outer ring. The inner hard-rubber rings are rigidly connected so that they must always rotate together. Pointers attached to these rings indicate the angle moved through upon semi-circular dials on the sides of the instrument.

Each of the condensers consists of 43 glass plates, 8 in. square, coated with tin-foil 7 in. square. The plates vary in thickness from 1/32 to ¼ in. The thicker plates are, of course, used for the smaller capacities. The plates are divided into groups of suitable capacity, ten leads being taken off from the front of the condenser and nine leads from its inner side. As will be seen from Fig. 1, the number of sections used can be varied at will by means of a fan-shaped contact. There are similar contacts on the inner sides of the condensers, directly under the spark-gap, which cannot be seen in the photograph.

The electrical circuit of the instrument is shown schematically in Fig. 2. r_1, r_1', r_2 and r_2' are the outer and inner circles of the variable

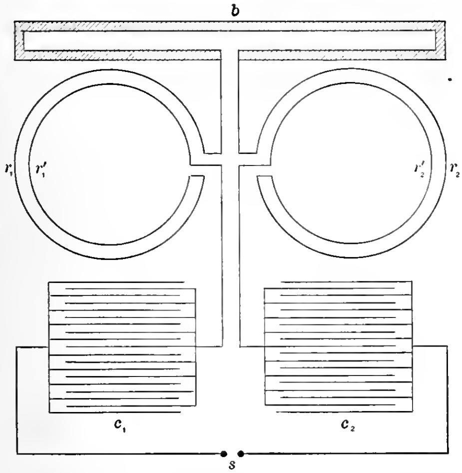

FIG. 2.—SCHEMATIC DRAWING OF THE CIRCUIT OF THE STANDARD.

inductances; c_1 and c_2 are the variable condensers; s is the spark-gap used to excite the system and b the *contact bar*, to which the circuit whose wave length is to be measured, is attached. Both parameters of the circuit, viz.: its inductance and its capacity, are variable. Its resistance can be neglected.

CALIBRATION OF THE STANDARD.

The calibration was made by means of Lecher wires. Two No. 10 bare-copper wires were stretched parallel to each other at a distance of 6 in. apart, and about 4 ft. above the floor, between the end walls of a loft 122 ft. long. The loft was about 50 ft. wide and divided by three rows of wooden pillars into four alleys. The parallel wires were stretched in the middle of each alley, and connected by cross wires at alternate ends, making the total length of parallel wires about 500 ft. (See Fig. 3). They were subdivided into lengths of 12 ft. or less by cutting the wires, making loops at the ends, and tying these ends together with short pieces of heavy cord. When desired, the cuts could be bridged with short pieces of the same wire fitting snugly into the loops. In this manner the parallel wires could be made of any desired length.

To perform the calibration the parallel wires were attached at one

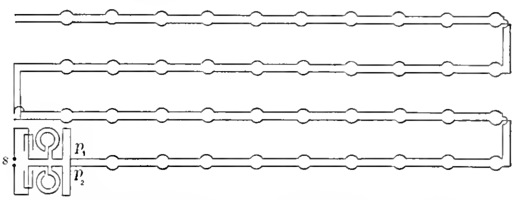

FIG. 3.—DIAGRAM SHOWING THE ARRANGEMENT OF THE LECHER WIRES BY MEANS OF WHICH THE STANDARD WAS CALIBRATED.

end to the points p_1 and p_2 on the "contact bar" of the standard (see Fig. 3). The standard was then excited with a small induction coil, causing a spark to pass between the balls of the spark-gap, s. This sparking produced electrical oscillations in the standard, and also in the Lecher wires, since they were attached to it. A Geissler tube was then placed across the free ends of the parallel wires, and the capacity of the condensers of the standard varied until the tube began to glow. The final adjustment was made by rotating the movable coils until the glow became a maximum. The standard and the Lecher wires were then in resonance; and the *quarter wave length* of the standard was equal to the length of the parallel wires. This process was repeated some fifty times, starting with the wires 40 ft. long, and increasing their length a few feet at a time up to 500 ft. The results are shown in the *calibration curve,* Fig. 4. It will be seen that the curve is made up of twelve sections, each section corresponding to a certain number of condenser leads. For the first section of the curve, we have *one* front lead, and *one* side lead; for the second section *one* front lead and *two* side leads; for the third section *two* front leads and *two* side leads, and so forth. Both condensers must, of course, have the same number of front and side leads. The readings in degrees on the dials are plotted as abscissas,

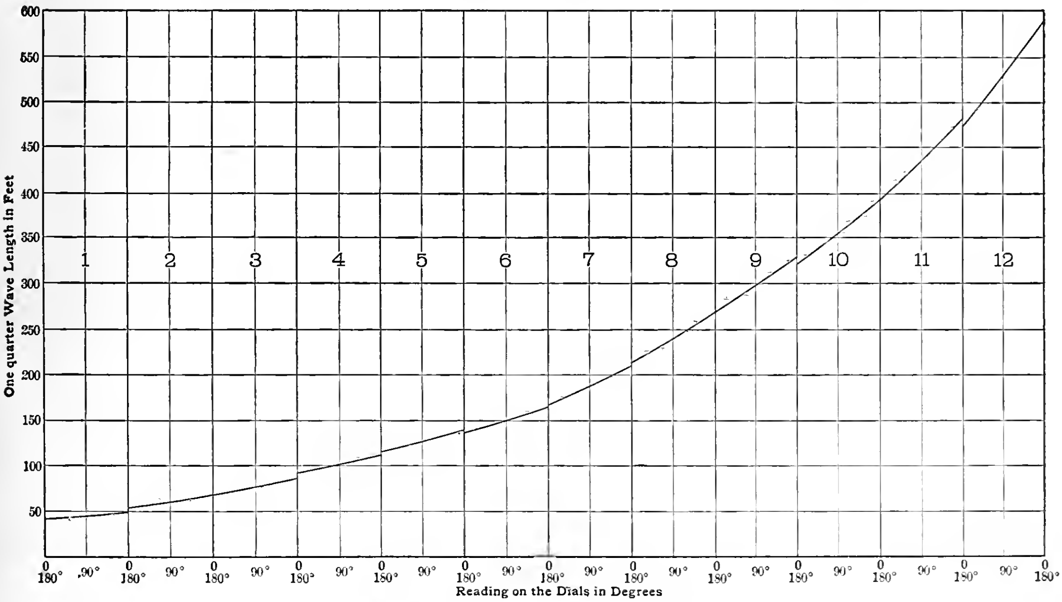

FIG. 4.—CALIBRATION CURVE OF THE STANDARD.

[illegible] quarter wave lengths as ordinates. The curve is broken as it was difficult to adjust the capacities of the successive sections of the condensers, so that the different sections of the curve would fit on to each other.

To test the accuracy of this experimental calibration, the quarter-wave length of the standard was *calculated* for each section, for the movable coils in the position of maximum inductance. This necessitated the measurement of the capacities of the sections of the condensers, and the calculation of the maximum inductance of the concentric circles. The results are given in Table I and show that the observed and calculated values differ from each other only by a few per cent.

TABLE I.

No. of section of curve	Capacity in microfarads of the two condensers in series.	Maximum quarter-wave-length in feet. Calculated.	Observed.
1	.0248	586	587
2	.0174	490	478
3	.0116	409	390
4	.00815	336	328
5	.00525	269	267
6	.00325	212	208
7	.00204	167	163
8	.00149	144	138
9	.00091	112	110
10	.00054	86	85
11	.00037	63	67
12	.00022	54	50

The maximum quarter-wave length was calculated from the formula

$$\lambda = 2\pi v \sqrt{L C}, \tag{1}$$

where

λ is the wave length,

v, the velocity of propagation of electric waves, taken in this case as 3×10^{10} cm. per second,

L, the maximum inductance of the standard,

C, the capacity of the number of sections of condenser used.

The inductance of the standard is, of course, equal to the sum of the two inductances, and its capacity equal to half that of either condenser. The total maximum inductance of the standard was found to be equal to 5,830 absolute units or abhenries. This is made up of two parts, viz.: the inductance of the concentric circles, amounting to 4,910 abhenries; and the inductance of the rest of the circuit amounting to 920 abhenries. The minimum inductance of the concentric circles was found by calculation to be equal to 2,670 abhenries. The total inductance of the standard, therefore, when the circles are in the position of minimum inductance is relatively large and equal to 3,590 abhenries. This accounts for the large initial ordinate of each section of the calibration curve.

The inductance, L, of formula (1) is made up of six parts, as follows:

$$L = L_1 + L_2 + 2 M_{12} + L_3 + L_4 + 2 M_{34} \tag{2}$$

where

L_1 is the inductance of the left-hand outer circle,
L_2, the inductance of the left-hand inner circle,
M_{12}, their mutual inductance,
L_3, the inductance of the right-hand outer circle,
L_4, the inductance of the right-hand inner circle,
M_{34}, their mutual inductance.

But since $L_1 = L_3$,
$L_2 = L_4$,
and $M_{12} = M_{34}$,

formula (2) reduces to

$$L = 2 L_1 + 2 L_2 + 4 M_{12}. \tag{3}$$

It was found by calculation that

L_1 = 1,038 abhenries,
L_2 = 855 abhenries,
and M_{12} = 280 abhenries

To calculate L_1 and L_2, the following formula was used:

$$L = 4\pi R \left(log_e \frac{R}{g} + .08 \right) \tag{4}$$

where R is the radius of the circle and g the radius of the wire, both in centimeters.

To calculate M_{12}, the formula for two concentric circles was used, viz.:

$$M = 4\pi R \left(log_e \frac{R}{d} + .08 \right) \tag{5}$$

where R is the radius of the inner circle, and d the distance between the two circles, both in centimeters.

METHOD OF USE.

The standard may be used to determine the wave length of a closed circuit or of an open circuit, e. f., of a tuning coil, or of an antenna.

To determine the wave length of the closed circuit, $A S C$, shown in Fig. 5, we open it at some convenient point and attach it to the "contact bar" of the standard at the points p_1 and p_2. It is now linked to the circuit of the standard, and when electrical oscillations are set up in the standard by a spark at S, oscillations both of current and potential will be produced in it, if its resistance be not too great. The amount of the current oscillations will be shown by the reading of the hot-wire ammeter, A, placed in the neighborhood of a current loop. When the two circuits have the same period of oscillation, the disturbance in each, by the principle of resonance, will have a maximum value. The inductance and capacity of the standard are, therefore, varied until a *maximum* deflection is obtained on the ammeter. The wave length of the standard is then equal to that of the unknown circuit.

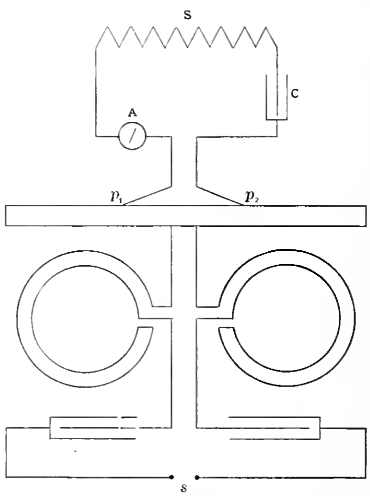

FIG. 5.—DIAGRAM SHOWING MANNER OF ATTACHING A CLOSED OSCILLATING CIRCUIT TO THE STANDARD.

The amount of the electrical disturbance of the unknown circuit can be regulated by varying the distance apart of the points of attachment, p_1 and p_2, on the contact bar. By bringing these points together, the reading on the ammeter may be made as small as desired.

The connecting wires from the unknown circuit to the contact bar should be heavy, and as near to each other as possible, so as to reduce the inductance of this part of the circuit to a minimum. If insulated, they may advantageously be twisted together. The "contact bar" is relatively heavy and the inductance introduced by it into the unknown circuit can usually be neglected.

To measure the wave length of an open circuit, such as an earthed antenna, we cut the wire at some convenient point, near to the earth plate, and link it to the standard, as shown in Fig. 6. In the figure, p_1 and p_2 are the points of attachment to the contact bar; a is the aerial wire; E the earth plate, and A the hot-wire ammeter.

GENERAL REMARKS.

This form of standard is compact and covers a large range of wave lengths. One advantage of the symmetrical form is that it can be calibrated by Lecher wires, these affording a simple and accurate means of calibration.

In its present form the inner circles of wire rotate about a common horizontal axis, and, since they are rigidly connected together, are always in the same plane. Their mutual induction, therefore, remains constant as they rotate. In an earlier form the inner circles were made to rotate about *vertical* axes, and consequently were not always in the same plane. This introduced a variable mutual inductance which disturbed the calibration curve in a peculiar manner, especially for the longer wave lengths. In these sections, the curve became steeper and steeper up to about 120°, and at this point became so indefinite that it was impossible to plot it farther. This trouble disappeared at once when the present arrangement was adopted.

To determine the condition of resonance, both a spark-gap and a Geissler tube were used across the ends of the parallel wires and were found to give the same results. Neither the Geissler tube nor the spark-gap appeared to have any appreciable effect upon the wave length of the wires.

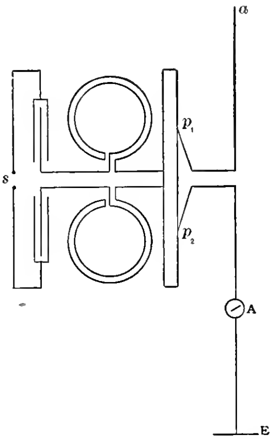

FIG. 6.—SHOWING THE WAY IN WHICH THE STANDARD IS LINKED TO AN ANTENNA IN ORDER TO MEASURE ITS WAVE LENGTH.

Lecher wires are in resonance with any given circuit, if their length is equal to one-quarter of the wave length of the circuit, or to an odd number of quarter-wave lengths. In determining the wave length of a circuit by measuring the length of the parallel wires, most accurate values are obtained by making the wires three or more quarter-wave lengths long, and measuring the distances between the nodes. Some values for the standard obtained in this way, I found to be greater by two or three per cent. than those obtained by using a single quarter-wave length. Since in calibrating the standard I used a single quarter-wave length in each case, the values given in the calibration curve are probably too small by two or three per cent. This supposition is borne out by the difference between the observed and calculated values given in Table I.

In making these measurements, no trouble was experienced from the presence of overtones. In fact, I did not observe any.

I wish to express my thanks to Mr. James B. Gottsberger for his assistance in this work.

Water Power in Germany.

Mr. Langer, U. S. Consul at Solingen, Germany, reports that the German Government is planning water power development in Germany on a large scale, the intention being to find out what there is in the country as to water power and to what extent the same is being utilized. Besides compiling the water level observations since the year 1896, water volumes shall also be ascertained, and furthermore it is intended to obtain information as to the power used by manufacturing plants gaining their energy from water power. It is also suggested to find out how much water power is used for each particular industry, as well as for agricultural purposes. This, in turn, would show which branches of trade should receive the first attention in having water supplied to them for power purposes.

Efficiency Curves of Rotary Converters.

BY A. S. MCALLISTER.

IN connection with the article by Dr. Kennelly on the "Efficiency Curves of Constant-Potential Transformers" and the editorial comment appearing in the ELECTRICAL WORLD AND ENGINEER for April 16, 1904, and the subsequent discussion thereof by Prof. H. S. Carhart, the following facts concerning the curves of rotary converters may be of interest.

Due to the simultaneous operation of a rotary converter, both as a motor and as a generator, the field distortion from the motor action is to some extent counteracted by that from the generator action, so that under proper field excitation, the field strength remains quite approximately constant throughout a great range of load. Hence, the armature iron loss varies but slightly with the load and, with a degree of accuracy fairly equivalent to that obtaining with constant potential-transformers, the iron loss may be considered to be independent of the load current. The variable loss is due almost exclusively to the copper loss in the armature winding.

The rotary converter with constant impressed alternating e.m.f. considered as a direct-current generator, tends always to produce the same direct external e.m.f. The apparent measurable pressure, however, drops off as the load is applied, due to the copper loss of the armature, and such drop is a direct measure of the loss within the armature.

At any chosen value of load current the sum of this loss in watts added to the output watts of the converter gives a value which would be directly determined by the product of the direct e.m.f. at its no-load value and the load current at its chosen value. It thus appears that with load amperes plotted as abscissas and watts as ordinates the curve of armature output plus copper loss due to load current is a right line and may be drawn at once for any value of output current (Fig. 1). The ratio of the watts loss in the armature copper, due to any load current, to the value of the load current gives the effective value of the armature resistance.

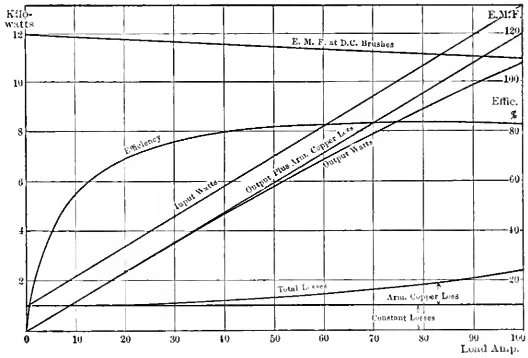

FIG. 1.—CHARACTERISTICS OF ROTARY CONVERTER.

Knowing the no-load losses of the converter and the effective armature resistance the complete performance may be calculated as follows:

Let W = no-load watts input,
R = effective armature resistance,
E = no-load direct e.m.f.,
I = any chosen value of load current;

then I^2R = copper loss of armature due to load,
$E - IR$ = apparent external direct e.m.f.,
$W + EI$ = input,
$EI - I^2R$ = output,

$$\frac{EI - I^2R}{EI + W} = \text{efficiency,}$$

which becomes a maximum when $I^2R = W$, *as a close approximation.*

It should be noted that the losses are $W + I^2R$, and that while the ratio of EI to $W + I^2R$ is a maximum when $I^2R = W$, at any armature load current, I, the input is $IE + W$ and not simply IE, as was given in ELECTRICAL WORLD AND ENGINEER April 30, 1904, page 824.

The above equations are based on the assumption of constant iron, friction and windage loss, which assumption is closely exact as stated above. In addition to these losses, the value, W, includes the armature copper loss for the no-load current, and the field copper loss for exciting current. Since for efficient service the exciting current should have a constant value, it follows that the loss from this source decreases as the machine is loaded due to the fact that the direct voltage decreases, requiring less loss in the regulating rheostat. The no-load armature current is of totally an alternating nature and traverses the whole armature winding, and during a portion of its route through the armature is superposed upon that part of the alternating supply current, which is about to be converted to direct current. While its effect alone upon the armature resistance would give a constant value of loss, when the two currents intermingle their combined loss is greater than the sum of the losses of the two considered separately, since in any case $(x + y)^2$ is greater than $x^2 + y^2$. It is thus seen that, among the losses which have a practically constant value, one increases with the load while another decreases, tending somewhat to keep the total at a constant value.

From the above facts and equations it appears that the curves of *constant losses, variable losses, output, input* and *efficiency* may be constructed from the two value, *no-load input* and *effective armature resistance* (Fig. 1).

Due to the fact that the alternating current of the motor portion of the converter flows in general in a direction opposed to that of the direct-current generator portion, the effective armature resistance for polyphase converters is less than that of the same machine used as a direct-current generator. The ratio of effective armature resistance to its true generator value is as follows:

2	rings converter,	1.39
3	" "	.56
4	" "	.37
6	" "	.26
8	" "	.21

Fig. 1 gives graphically the results of calculations of the characteristics of a certain rotary converter of which the no-load losses are 1,000 watts and effective armature resistance .125 ohm.

The major portion of what has been given above applies in general to shunt-wound generators or motors, but the assumption of constant armature iron loss is less exact with the later machines than with the rotary converter.

Governmental Control of Wireless Telegraphy.

The report from Washington that the Cabinet, co-operating with the Navy Department, had decided to assume control of all wireless telegraph stations on the coast line of the United States and operate them in the public service in connection with existing land wire systems has been contradicted. Secretary Moody, of the Navy, is quoted as saying: "The newspaper article probably has reference to the authority granted by this department to the Bureau of Equipment for the use of the naval wireless telegraph stations as an accommodation to ships of other navies and the merchant service where there are no commercial stations to receive and transmit messages. As a result of negotiations with the various land telegraph companies, the Western Union and Postal Telegraph Companies have agreed to transmit messages of the character above mentioned received at naval wireless telegraph stations from vessels at sea without holding the government responsible for the toll."

Captain Manney, chief of the Bureau of Equipment, says: "The Government will not in any way interfere with the Marconi station on Cape Cod. These stations have a range of not more than 240 miles out to sea and are for the general convenience and safety of the public, in a broad way supplementing the work of the Hydrographic Office. The reason for taking control of the stations and placing them under one system is to prevent interference on short-distance messages. Arrangements have been made by the Govrnment with both the Western Union and Postal Companies under which the Government turns over to these companies all private dispatches received and the same will be forwarded without prepayment. The system employed by the Government is a modification of the Slaby-Arco, known as the Telefunken, and is used by the German navy entirely."

An English Municipal Electric Railway.

On May 18 the municipal tramway line of Leicester, England, was declared open for public use, having been under construction since April of last year. The system will eventually comprise 19½ miles of double and 3½ miles of single track. Of the equivalent of 42 miles of single track, 33 miles are now completed and work on the remainder progressing. The routes are moderately straight and with no excessive grades, the steepest being 1 in 16 for a distance of about 50 yards. It has been found necessary, however, to lower the roadway under seven railway bridges, in one case as much as 2 ft., in order to obtain sufficient head room for double-deck cars.

The sharpest curve on the system is 37 ft. radius to the center of

FIG. 1.—ENGINE ROOM, POWER STATION.

the track. A minimum radius of 40 ft. for all curves was aimed at, and with one or two exceptions this has been attained. The distance from center to center of tracks with side pole construction is 8 ft. 1 in., giving 3 ft. 4½ in. from gauge edge to gauge edge between tracks, and for center pole construction 10 ft. 11½ in., giving 6 ft. 3 in. between tracks. The gauge of the track is 4 ft. 8½ in.

In laying the track the ground was excavated to the required depth, and the rails laid and packed up to the required level on wedge-shaped blocks of concrete, 10 in. square at the base and 8 in. square

FIG. 2.—EXTERIOR OF POWER STATION.

at the top. Where bad ground was met, or the surface worked up owing to inclement weather, these blocks were again supported on circular blocks of concrete, 6 in. thick and 18 in. in diameter, to distribute the weight over a greater area. When the rails were leveled up, a concrete foundation, composed of six parts of granite and Destructor clinker to one part of best Portland cement, was then laid, a space of about 1 in. being left under the rails for packing, great care being taken to make the concrete perfectly solid for a space of 6 in. on each side of the flange of the rails. The space between the concrete and the rails was then very carefully packed by means of beater picks with 6 to 1 fine concrete in a semi-dry condition. The total depth of concrete under the rails is 7 in., and under the paying 6 in.

Two solid copper "Crown" bonds of No. 4/0 B. & S. gauge are inserted at each rail joint. The track is cross-bonded every 40 yards and the two tracks every 80 yards.

The power station has been erected centrally to the system, and it is well situated for the delivery of coal either by barge (the canal basin running alongside the boiler house), or by rail. The buildings are faced externally with red sandstock bricks with stone dressings, copings, etc. The station comprises engine room, boiler room, pump room, condenser room, battery room, test room, engineer's office, general office, inquiry office, mess room, fitting shop, stores, engine house lavatory and office lavatory. Bath rooms have been attached to the two latter.

The engine room is 118 ft. by 60 ft. and 40 ft. high to the eaves. It is lighted mainly from the top by means of patent glazing, which has also been used in the fitting shop and battery room. The only side lights in the engine room are bull's-eye windows above the traveler rail. The room is lined internally up to the height up the traveler rail with glazed tiles having patent keyed backs, moulded tiles being carried up to a height of 6 ft. to form a dado. Moulded tiles are also carried round all the arches, wtih moulded faience blocks under the traveler rail. This tiling gives the room a very fine appearance. The entrance hall and the floor in the engine room, except the space reserved for the extra set, have been laid in mosaic.

The boiler room is 108 ft. by 77 ft., and a stoking floor 18 ft. wide extends its full length with an ash tunnel under. At present the stoking floor is covered with a temporary corrugated iron roof. The boiler room has been so arranged that when the coal is delivered by barge alongside it will be lifted by a crane fixed at the northwestern end of the boiler house into a conveyor, and conveyed into the coal bunkers. The conveyor will be continued round and through the ash tunnel for the removal of the ashes. The boiler

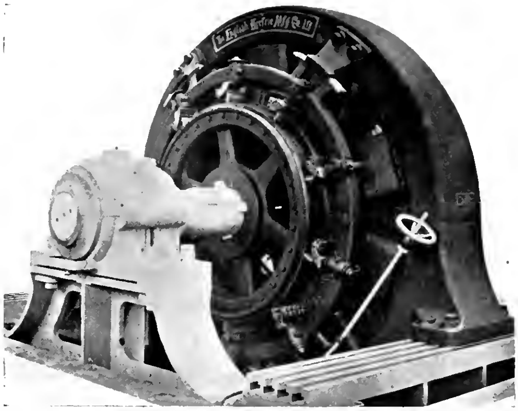

FIG. 4.—ONE OF THE GENERATORS.

house is lighted principally from the roof by means of patent glazing. Windows have also been inserted in the southwestern elevation.

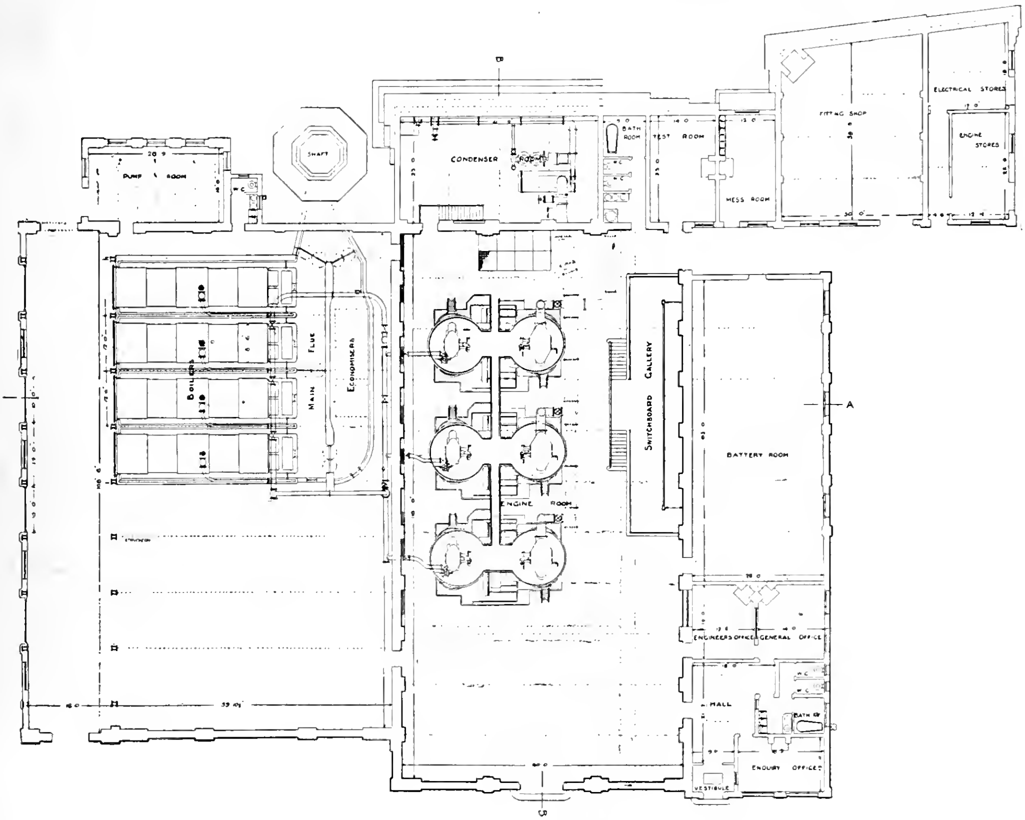

FIG. 3.—PLAN OF POWER STATION, LEICESTER MUNICIPAL TRAMWAY.

Kinnear rolling shutters have been inserted in the doorways opposite the fronts of the boilers.

The generating outfit consists of three 500-hp Gates & Thorn vertical cross-compound Corliss condensing engines, direct-connected to the same number of Dick & Kerr railway generators. In addition with the ordinary governor, which [illegible] very sensitive one, the engine is fitted with a special safety stop which will operate in case the engines reach a speed of 10 per cent. above the ordinary working speed. It will also stop the engine in the event of any failure of the governor gear, although it does not interfere with the engine taking excessive overloads, even beyond the full range of the cut-

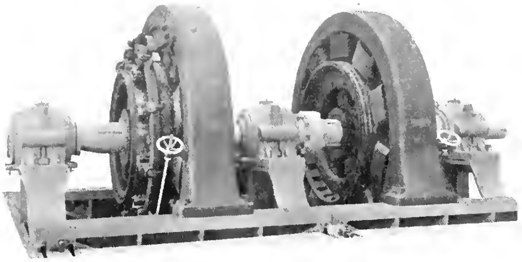

FIG. 5.—BOOSTER.

off gear. The fly-wheel is 16 ft. diameter, and weighs about 25 tons. A very complete system of lubrication has been supplied to these engines, consisting of two ram pumps worked by a drag shaft from the main cranks, and delivering oil under pressure to all the main bearings about the engines.

The switchboard, which was also supplied by Dick, Kerr & Co., consists of twenty-five panels of white marble, controlling, besides the three 500-kw generators, a negative feeder booster set of 20-kw capacity, a positive feeder booster set of 60-kw capacity, an automatic reversible battery booster set of 40-kw capacity, the station lighting and motors and the distribution.

The battery is composed of 240 cells of the Standard Tudor pattern type No. 413 HF 19. It is capable of giving 600 amp. for one hour, or 900 amp. for short periods, and can be charged normally at 270 amp., or at 450 amp. for short periods. The cells are in lead-lined wood boxes, resting on glass oil insulators. The stands are entirely of pitch pine without any metal fastenings, and rest on large porcelain oil insulators. The battery is used in connection with a reversible booster controlled by means of a Thury's patent regulator. This booster has a smooth armature core and tangential

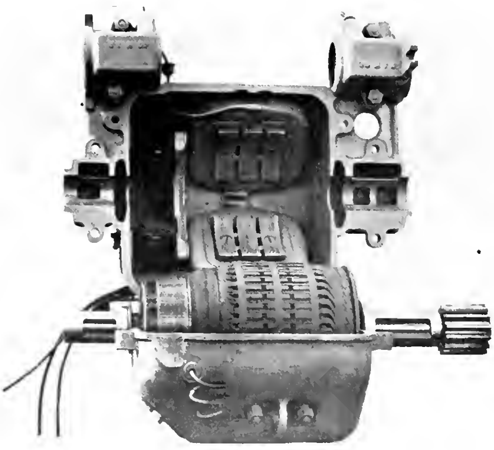

FIG. 6.—VIEW OF INTERIOR OF CAR MOTOR.

field coils. As the armature winding is placed as near as possible to the periphery, and as the field iron is reduced to its possible minimum amount, the machine is most sensitive, and is claimed to act almost as quickly as the load peaks occur.

The overhead equipment has been designed and arranged with a view to obtaining the greatest possible immunity from break-down, also that the fittings should appear as artistic as possible. The design of pole ornamentation was prepared by Mr. Mawbey in conjunction with the Leicester Art School. Span wire construction has been adopted generally, but where streets and roads are wide enough center poles have been introduced, as shown in Fig. —. In the center of the town, where suitable attachments could be obtained, poles have given way to rosettes, except at junctions, these being erected on poles throughout. Each center pole has been fitted with two incandescent gas lamps, and the vase is protected by a neat elliptical guard curb. Side bracket arms have been used on one short length to the number of nine, each 17 ft. 6 in. long, also on the siding to the power station.

The trolley wire is No. 000 B. & S. gauge throughout, except at the car houses, which are wired with No. 0; and the span and guard wire are of galvanized steel, 7-12 and 7-16 respectively. Flexible suspension and double insulation have been adopted throughout. Line fittings of extra strong design have been used throughout, the insulator bolts being of drop-forged mild steel, screwed ¾ in.

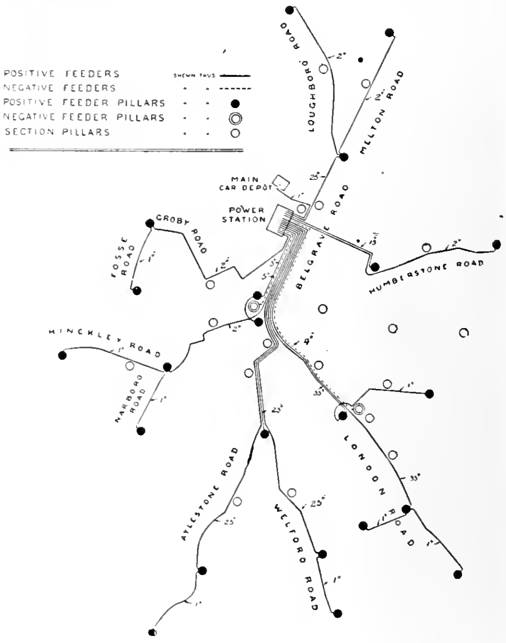

FIG. 7.—PLAN OF FEEDERS.

Four sizes of section and feeder pillars are used. These are fitted with white marble panels, which carry the various quick-break switches, kicking coils and safety fuses for automatically disconnecting the overhead line in case of failure. The feeders are connected up to the main switchboard at the power station through automatic circuit-breakers, which are set to cut out any one of the feeders should a short-circuit occur on any of the sections supplied by that feeder, thus insuring that should a trolley wire break on any portion of the line either the fuses in the nearest section pillars would "blow," or the circuit-breaker at the station would open, rendering that portion of the line dead. Each pillar is also fitted with a Garton lightning arrester, and an ebonite panel carrying the test and telephone terminals. All holes in the panels are fitted with ebonite bushes and washers.

A specially designed telephone shutter, operated by a separate key, has been fitted to each pillar, arranged so that it is unnecessary to open the pillars in order to use the telephone, the jack being inserted from the outside, thus obviating the danger of any one accidentally coming in contact with the "live" fittings in the pillar when using the telephone. The telephone instruments are carried on the cars, one being supplied to each car.

Two negative feeder pillars are erected to meet the present requirements, approximately 1,100 yards and 2,700 yards, respectively, from the power station. They contain the usual instruments to meet the Board of Trade requirements. All section and feeder pillars, and the poles up which the feeder cables have been carried, are bonded direct to the rails by a 4/0 copper bond, to prevent the possibility of their becoming "alive" owing to break-down of the insulation at these points. The whole of the equipment, including poles, wires, section and feeder pillars, etc., have been supplied and erected by R. W. Blackwell & Co.

All of the cables in connection with this work were supplied and drawn in by W. T. Glover & Co., Limited, of Manchester. Stoneware conduits are used, and are of the patent self-centering type with composition joints. The total quantity of conduits supplied was equivalent to about 80,000 yards of single-way. Throughout the entire system the conduits are laid at the side of the track. The cables are single conductors, insulated with diatrine impregnated paper and lead-covered, jointed by means of lead sleeves wiped on to the lead of the cables. At intervals of approximately ¼ mile the lead covering of the cables is earthed to the rails by means of bare copper bonds, as a preventitive against electrolysis.

Three negative feeders have been carried out to different points of the system, and are connected to the rails through special feeder boxes. Each cable bears a brass label in every box, denoting its size, voltage and termination. The sizes of the feeders range from

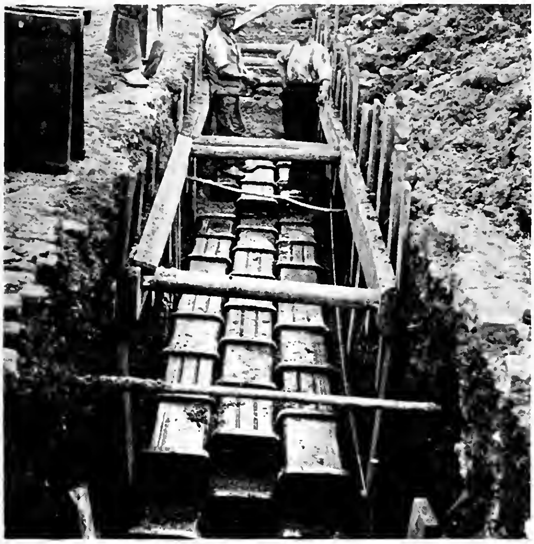

FIG. 8.—CONDUITS AT ENTRANCE TO POWER STATION.

.1 sq. in. to .5 sq. in., the total length being over 20 miles. A complete system of telephone and pilot cables is also drawn into separate ducts along each feeder route, and connected up in every feeder and section box.

All lead-covered cables terminate in the basement of the power station; connection being made to the switchboard with fire-resisting cable of Glover's latest type. In addition to the feeder cables terminating on the switchboard with fire-resisting cable, the whole of the back connections and cable work in the station is also of this description. All of the feeders and pilots were submitted to a pressure of 1,000 volts alternating current for one hour. They were then tested for insulation resistance.

N. E. L. A. Membership.

At the Boston meeting of the National Electric Light Association, which was held last week, an amendment to the constitution was adopted dividing the membership in five classes, as follows: Class A, member companies; entrance fee, $25; annual dues, companies in towns of less than 20,000 population, $10; 20,000 to 300,000, $25; over 300,000 population, $50. Class B, members; entrance fee, $5 and annual dues $5. Class C, associate member companies; entrance fee, $25; annual dues, $20. Class D, associate members; entrance fee, $5 and annual dues, $5. Class E, honorary members; no entrance fee; annual dues, $4.

Electric Transportation Within the World's Fair Grounds.

By CLOYD MARSHALL.

NEW problems of transportation arise as each international exposition grows in extent, and these have been met at St. Louis in several ways. The first and most important means of transportation about the grounds is by the intramural railway, which is a complete electric railway system consisting of seven miles of double track encircling the grounds and running nearby each important building. Its operation is similar to that of an elevated railway with stations at convenient points and a uniform fare of ten cents for all or any part of the trip. Such a means of communication is a real necessity, not simply catering to the pleasure to the visitors. This has recently been demonstrated. The intramural track has formed an important portion of the railroad system within the grounds. Since the Exposition opened, all cars with exhibits and materials have been switched on the sidings or into the buildings at night. To permit this the intramural cars have ceased running at 10.00 o'clock, which is about the time when the visitors are enjoying the amusement features of the Pike. Those who wish to return to the Inside Inn or go to the opposite entrances have to walk about two miles, and, therefore, have made loud objections to the intramural schedule. A complete circuit around the grounds by means of the intramural railway is perhaps the best introduction to the whole Exposition that the visitor can have. He will be im-

FIG. 1.—LAUNCH ON THE LAGOONS.

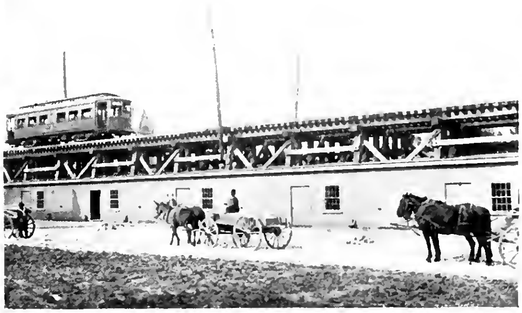

FIG. 2.—ELECTRIC RAILWAY IN GROUNDS.

pressed by the vast extent of territory covered, the beautiful arrangement of the grounds, and the size and number of the Exposition buildings.

A trip which is even more enjoyable and instructive is one on an electric automobile through the heart of the Exposition. This is the first World's Fair at which such a service has been rendered, and the generous patronage received indicates that it meets an actual want. The World's Fair Automobile Transit Company has secured a large number of electric vehicles and will have over one hundred later in the season. This service has been available for over a year. As many as 3,500 persons have patronized the automobiles in one day during the pre-Exposition period. The regular route covers the center of the Exposition and a visit to each of the exhibit palaces. At intervals a stop is made, and the chauffeur explains those things which interest his passengers. A fare of twenty-five cents is charged.

If the visitor wishes the exclusive [illegible] vehicle, he can hire a cab or brougham at a rate of $4 per [illegible] and take his friends to any part of the grounds he may desire. There is but one forbidden roadway, which is between the Louisiana Purchase Monument and the Grand Basin, and over this no vehicles can pass.

The company also has a number of large automobiles running from the principal hotels in the city into the Exposition grounds. The fare for this ride is 50 cents. Arrangements are also made to meet parties or delegations at the trains and convey them to the grounds or to the Inside Inn. A special gate into the grounds is provided for the automobiles. The automobile service begins at 8.00 A.M. and continues until 1 o'clock at night. While the intramural is not running after 10 o'clock, about ten automobiles are used at night carrying the pleasure seekers on the Pike to the Inside Inn or to the distant entrances. In order to reduce the fire hazard, all gasoline automobiles are excluded from the grounds, which leaves the field exclusively to storage battery vehicles. The World's Fair Automobile Transit Company had no precedent by which to gauge the needs of such service, and had no standard of equipment. There are a number of different types of vehicles in use, some of which have been acquired from the Buffalo Transportation Company, the Boston Auto Express Company and others, the vehicles being modified to suit the local conditions. One of the landaus in use was that which conveyed President McKinley to the Music Hall at the Pan-American Exposition before his assassination.

FIG. 3.—STATION ON ELECTRIC RAILWAY.

FIG. 5.—VIEW ALONG THE TRACK.

FIG. 4.—A CAR ON THE ELECTRIC RAILWAY.

FIG. 6.—LARGE AND SMALL AUTOMOBILES ON GROUNDS.

Recently a number of large tally-hos seating forty persons have been put in service between the grounds and the hotels. The Electric Vehicle Equipment Company has furnished a number of buses with a capacity of eighteen passengers. Fifty 20-passenger brakes are now being delivered by the Auto Car Equipment Company, of Buffalo. Not less than thirty cabs, landaus and broughams are to be in commission. The automobile company has made an excellent record, as not one accident of any kind has occurred with their vehicles. This is due largely to a rigid system of inspection to keep the automobiles in good condition, and to the careful instruction of all its operators. There is no prescribed speed regulation, because fast driving would defeat the purpose of the trip, which is to give the passengers a chance to comprehend the beautiful surroundings. The automobiles seldom if ever exceed eight miles an hour. Each driver must be an experienced chauffeur and before taking charge of a vehicle is tutored by an instructor with reference to the care and operation of the automobile and also regarding the fact and figures about the exposition which will be of interest to his future passengers.

The company has built a garage and charging station at the east end of the Model City and near the De Forest tower. Three 50-hp gas engines are belted to Edison 110-volt generators to supply the current. The leads extend to the charging plugs along one side of the building where fifty-five batteries can be charged at a time. Another charging station is down town at the corner of Thirteenth and Locust Streets. There are two batteries or sets for each automobile, so that each vehicle can be kept in continuous service, one battery being charged while the other is in service. The battery is carried beneath the body of the automobile, and when it is to be leased the vehicle is run over a lift which is level with the floor. A wheel truck is pushed over the lift and under the battery. It is then raised to receive the battery, and when lowered is moved to a charging plug. There are four of these lifts operated by Ingersoll-Sargeant oil pumps driven by electric motors. Six batteries can be removed and replaced every ten minutes. The charging generators are kept at 110 volts, and the current charge to each battery is regulated by a rheostat. As there is an attendant at the generators and at the batteries all the time no automatic overcharge or release is employed. The batteries receive charges once a day, which is sufficient for a twenty-five-mile run. Once a week each battery is discharged under the observation of an expert and readings are taken every five minutes. Any necessary repairs or renewals are made at this time. When fully charged the density of the electrolyte is kept at 1,300, which falls to about 1,250 at the end of normal discharge. The plates for these batteries are shipped direct from the Electric Storage Battery Company and assembled and the connections burned together at the station. Wooden separators are employed as they seem to give better results than rubber. All batteries have forty-two "exide" cells, with from nine to nineteen M. V. plates, depending upon the size of the vehicle. The motors are

FIG. 7.—SMALLER PASSENGER AUTOMOBILE.

either General Electric or Westinghouse, of 80 volts and 20 to 35-amp. capacity, with series parallel control.

After a circuit of the grounds in an automobile has been made during the day, the visitor will find great pleasure in a launch trip about the lagoons during the evening. The most beautiful effect imaginable is during the illumination when the myriad lights on the buildings are reflected in the placid waters of the Grand Basin and lagoons. A journey of two and one-half miles can be made through the Grand Basin across the base of the Cascades around

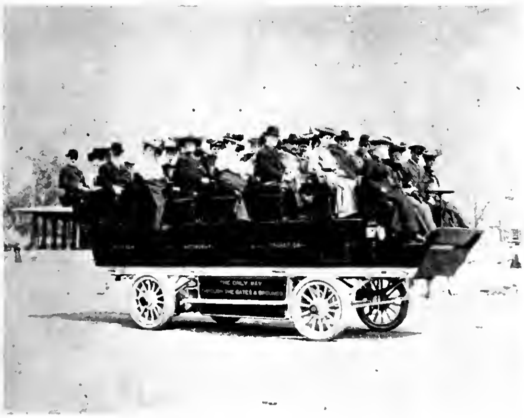

FIG. 8.—LARGE PASSENGER AUTOMOBILE.

the Palaces of Electricity and Education, and past the Machinery, Varied Industries, Manufacturers', Mining and German Buildings. During the daytime the launches are covered with awnings to make it comfortable for passengers in the heat of the day, but in the evenings the sun shades are removed. The Launch & Gondola Concession Company has thirty-one electric, five gasoline launches and fifteen gondolas. The gasoline launches are made in fantastic designs representing swans, peacocks, dragons, etc. The gondolas are imported direct from Venice and the singing Venetian gondoliers who accompany them have been selected both for their voice and for their skill with the oar. The launches are thirty-five feet in length and seven beam, and draw thirty inches of water when loaded. About forty passengers can be carried and the fare for the trip is twenty-five cents. The electric boats travel at the rate of four and one-half miles per hour and make the circuit in about a half hour.

The launches, which were made by the Truscott Boat Manufacturing Company, are equipped with Willard batteries. Each contains forty-four cells of 140-amp.-hour capacity, the positive plates having the new type Willard envelope, which gives excellent results by preventing to a great extent the shedding of active material. Each battery is divided into two parts, which by means of a Hertner

FIG. 9.—LAUNCH ON THE GRAND BASIN.

series parallel controller gives three speeds forward and two on reverse. The motors were supplied by the Hertner Electric Company and are of 2-hp, compound-wound, four-pole, with ball, thrust and axle bearings. On account of the slack water and the lagoons being sheltered from the winds, a boat will run 100 miles on a charge. At present they are in service from five to six hours a day, and the busiest time is from 5 to 10 P.M.

The charging station for the launches is under the bridge just west of the Electricity Building, from whence is received a 250-volt supply of current. Along the bank are leads to thirty-two Anderson automobile charging plugs, two batteries being charged on each circuit. At the switchboard are the wattmeter, volt and ammeters, pilot lamps

FIG. 10.—ANCHORAGE FOR LAUNCHES.

and Wirt rheostats for regulating the supply of current. Mr. H. B. Barnes, who is in charge of the station, has arranged the voltmeter and pilot lamp circuits so that he can tell at a glance the condition of charge of all batteries connected. The normal charge rate is 25 amp., and the charge is continued until the cells average about 2.55 volts. The electrolyte is maintained at a density of 1,250 at full charge and about 1,200 when the cell is discharged.

By a judicious patronage of the intramural, the automobiles, launches and roller chairs the visitors can cover the great area within the World's Fair grounds without undue fatigue or expense.

Performance of Parsons Steam Turbines.

In a paper read before the May meeting of the British Institution of Electrical Engineers, the Hon. Charles A. Parsons presented a paper on the steam turbine as applied in electrical engineering, which includes the data of a number of tests of electric turbine generating plants made by various consulting and central station engineers. Referring to the design of the Parsons turbine, it is stated that some of these were formerly made of the tandem type, in which the expansion of the steam was first carried out in a high-pressure cylinder and then completed in a low-pressure cylinder, but it was soon found that better economy, except possibly in very large sizes, could be obtained by having the whole turbine in one cylinder.

Fig. 1 is a curve from the paper showing the effect of varying vacua in the case of a turbine at Hulton colliery operating a 300-kw.

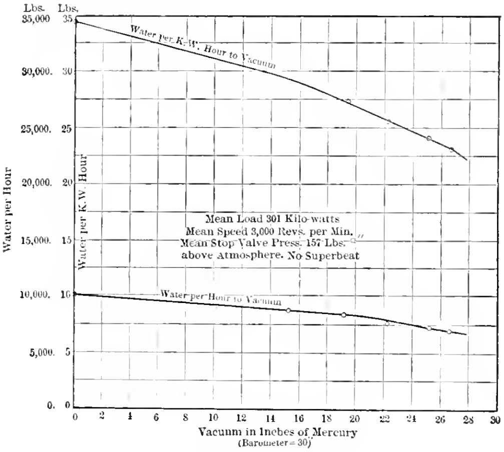

FIG. 1.—CURVES SHOWING EFFECT OF VARYING VACUA.

three-phase alternator. In Fig. 2 are curves from a 1,500-kw turbo-generator in the plant of the Sheffield Corporation, the turbine driving a two-phase alternator supplying current at 2,000 volts.

Mr. Parsons states that tests show that under the conditions of,

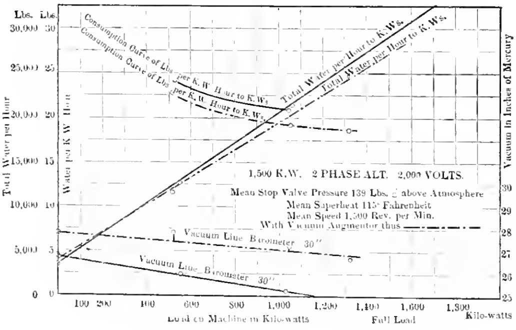

FIG. 2.—PERFORMANCE CURVES OF 1,500-KW TURBO-GENERATOR.

say, 140 pounds steam pressure, 100° F. superheat and a vacuum of 27 in. with the barometer at 30 in., the steam consumption of turbo-generators are, in round numbers, as follows:

A 100-kw plant takes about 25 pounds of steam per kw-hour at full load, which figures become 22 pounds for a 200-kw plant; 20 pounds for one of 500 kw; 19 pounds for one of 1,000 kw; 18 pounds for a 1,500-kw plant, and 16 pounds for a 3,000-kw plant. These figures are stated to be derived from averages of a large number of tests which have been made from time to time. Without superheat the consumptions are about 10 per cent more, and each 10° F. superheat up to about 150° F. affects the consumption by about 1 per cent.

In a turbine the benefit derived from the vacuum is much more than in a reciprocating engine, every inch of vacuum between 23 and 28 in. affecting the consumption on an average of about 3 per cent. in a 100-kw machine, 4 per cent. in a 500-kw machine and 5 per cent. in a 1,500-kw machine, the effect being more at high vacua than at low. The maintenance of a good vacuum necessitates a suitable condenser, which implies sufficient tube area and also ample way for the steam between the tubes; proper velocity of water in the tubes; sufficient supply of cooling water and a sufficient means of cooling the condensed water so as to keep the air pump cool, and full provision for extracting by the air pump and other means the inevitable small quantity of air which must leak in.

It is stated that by attention to these requirements it is unnecessary to increase the size of the condenser beyond that used in ordinary practice. In the case of the most recent condensers for steam turbines, from 10 to 12 pounds of steam are condensed per square foot per hour, at which rate of condensation a vacuum may be obtained at from 27½ to 28 in. at full load. The amount of cooling water generally allowed is about 50 times the full load steam consumption, which will increase the vacuum under normal conditions by about ¾ in. or 1 in. over that obtained by the usual circulating allowance of 30 times the steam used. With a proper arrangement of pipes and condensers in a plant taking 18 pounds of steam per kw-hour and assuming 50 per cent. efficiency in the pump and motor, the power used by the circulating pump is only 1 per cent.; by circulating water 30 times the steam consumption it would be .6 per cent., which small reduction is not to be compared with the gain of 4 or 5 per cent. in the turbine by the use of increased circulating water.

The paper described a vacuum augmenter which has recently been introduced and which is illustrated in Fig. 3. A pipe is led from

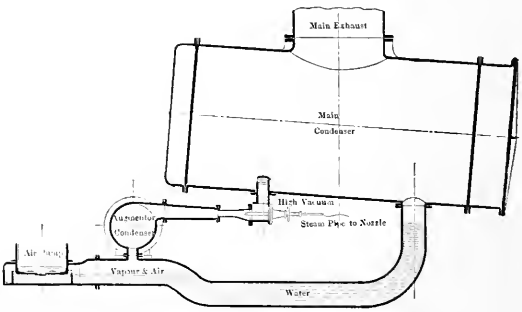

FIG. 3.—ARRANGEMENT OF VACUUM AUGMENTER.

near the bottom of the main condenser to an auxiliary condenser having generally about 1/20 the cooling surface of the main condenser. In a portion of this pipe a small steam jet is placed which acts in the same way as a steam exhauster and sucks nearly all the residual air and vapor from the condenser and delivers it to the air pumps. A water seal is provided, as shown, to prevent the air and vapor from returning to the condenser. With this arrangement, if there is a vacuum of 27½ or 28 in. in the condenser there may be only about 26 in. in the air pump, which, therefore, need only be of small size, the jet compressing the air and vapor from the condenser to about half or less of its original volume. The steam jet used only about 1½ per cent. of the quantity of steam used by the turbine at full load. Condensation takes place in the condenser much more rapidly and effectually if the air is thoroughly extracted.

In Fig. 2, which represents tests of the 1,500-kw plant at Sheffield, one curve was taken with and another without the vacuum augmenter in operation. The difference of vacuum is shown, and when it is remembered the augmenter jet took only about 1½ per cent. of the full load steam consumption, it is easily seen from the gain of vacuum where the total gain by the use of the augmenter comes in. In this case the vacuum was not as good as it should be, since the cooling water was at a temperature of 85° F., and was in volume only about 30 times the steam consumption at full load.

Referring to the design of dynamos and alternators to be coupled to steam turbines, it is stated that special regard is to be paid to the large centrifugal force to be encountered. Diameters have to be kept down, and excessive surface speed must also be avoided. Since then the diameter has to be small, the length must be increased in proportion and a long core is the result, with moderate diameter, the contrary of slow-speed machines. At the same time, on account of the higher surface speed, the pitch of the poles is greater, thus

giving more ampere-turns per pair of poles than is usual. In alternators this gives no trouble at all, as all that has to be provided is

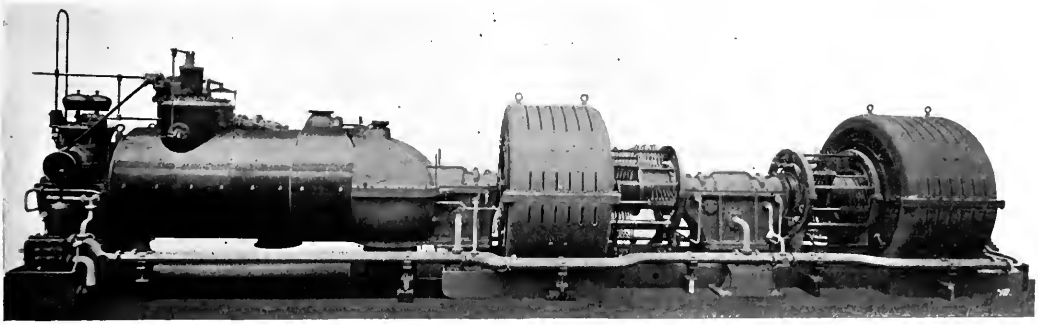

FIG. 4.—1,800-KW PARSONS TURBINE, MANCHESTER.

sufficiently strong field magnets to overcome the reaction of the armature, and sufficient magnetic resistance to allow of strong field magnets. This extra magnetic resistance can be given either in the air-gap or by saturation of the poles, as may be found desirable. These large poles also conduce to diminish magnetic leakage, and as a result very good regulation can be obtained.

In low-voltage alternators rotating armatures are preferable, as the iron and copper losses are much less, especially where there are only two or four poles, but rotating armatures, although satisfactory for 500 to 2,000 volts, have not been found suitable for the higher voltages of 6,000 and 10,000 which are now common, and therefore rotating fields and fixed armatures have been adopted in many of the recent alternators. For continuous-current dynamos the same remarks apply, only here sparkless commutation has to be provided for. Carbon brush blocks cannot be used, as at these speeds the brushes are apt to vibrate, and so diminish the intimacy of contact and cause heating and undue wear. The result is that it has been found best to form the brushes of wire, gauze or foil, preferably of brass, and these must be sufficiently flexible so as to maintain a good contact with the commutator over the whole section of the brush. It follows, therefore, that the properties of the carbon brush

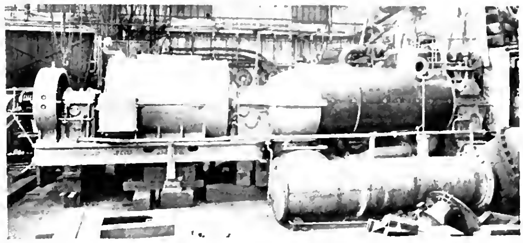

FIG. 5.—2,000-KW PARSONS TURBINE.

blocks in giving sparkless commutation without alteration of the lead of the brushes, cannot in turbine-driven dynamos be utilized, and other means must be adopted to secure sparkless commutation at varying loads. One way is to shift the brushes automatically according to the change of load, and this can be effected by connecting the brush gear to a steam cylinder controlled by a spring and supplied with steam from the point where the steam enters the turbine. At this point the pressure of the steam is proportional to the load of the dynamo, and therefore the piston in the steam cylinder being controlled by a spring takes up a position proportional to the load and thus shifts the brushes to the point of sparkless commutation. Another method is to provide commutating poles as proposed by Prof. Ryan and others, but the best method is to provide compensating winding as proposed by Prof. Forbes, Deri, etc. By these means, with the improvements recently adopted, absolutely sparkless commutation can be secured with fixed brushes, up to, in plants for traction purposes, 100 per cent. overload.

Mr. Parsons points out that the size of turbines is rapidly increasing, many of from 4,000 to 6,000-kw capacity now being in the course of construction, and it is anticipated that still larger plants will be made shortly. Up to the present there are about 600.000 hp of turbines of the Parsons type at work and on order in England and on the continent, in various sizes ranging up to 7,000 kw.

Electrical Interests at Panama.

A cable dispatch from Panama says that the electric light and tramway plants and telephone system in the Panama Canal zone have been bought by a syndicate in which American capital in interested.

Chicago Meeting of American Society of Mechanical Engineers.

The 49th meeting of the American Society of Mechanical Engineers, held at Chicago May 21 to June 3, was a joint meeting with the British Institution of Mechanical Engineers. The professional sessions were held in the evenings in the Music Hall of the Fine Arts Building and in the mornings in the Auditorium Hotel, with the exception of the last meeting, which was held on the morning of June 3 in the auditorium of Lewis Institute. The local committee had prepared for the use of members a pamphlet guide to points of interest in Chicago, and made very complete arrangement for the entertainment, both professional and social, for visiting members.

The meeting was opened on Tuesday evening by an address of welcome by Mayor Harrison, which was responded to by President Ambrose Swasey, of the American Society of Mechanical Engineers, and President J. Hartley Wicksteed, of the British Institution of Mechanical Engineers. The local committee carried out an elaborate programme for the entertainment of the ladies of the party, and half of each day was devoted to a visit to some point of professional interest in Chicago or vicinity. On Friday evening the local members of the American Society of Mechanical Engineers provided a special concert by the Thomas Orchestra in the Auditorium Hotel to visiting members of the American and British Societies.

Three of the papers on the programme were on the steam turbine, covering respectively the De Laval, Westinghouse-Parsons and Curtis types. The paper on the first-mentioned type was contributed by Messrs. E. S. Lee and E. Meden, the first part of which is devoted to a description in detail of the turbine. The applicability of this type of turbine for driving centrifugal pumps and blowers is pointed out. In both cases high velocities are required for good efficiencies, and with the De Laval turbine it is easy to produce the most suitable velocities. For lifts from 15 ft. to 150 ft. smaller turbines having one gear shaft may be employed, and for lifts of 40 to 300 ft. large turbines with gear shafts; for a greater lift the centrifugal pump has been directly connected to a high-speed turbine shaft, the pump wheel in this case revolving with a velocity of from 10,000 to 30,000 r.p.m. As the pump wheel in the latter case will naturally be very small and not produce any suction, it must be fed by another pump connected with the gear shaft running at a considerably reduced velocity. Pumps of this type have been made for lifts up to a normal head of 850 ft. on a single wheel and in some cases this type has been made for feeding boilers.

The Curtis turbine is represented by a paper contributed by Mr. W. L. R. Emmet. The claims for this type of turbine with respect to its rivals are treated at some length, and the paper contains a number of illustrations of the turbine as a whole and of some of its parts. It is stated that practically no troubles or interruptions have been caused by the step bearings, which have developed a ruggedness and stability far beyond the expectations of the designers. In newer designs, however, a powerful brake will be provided, bearing on the lower surface of a chilled iron ring carried by the lower wheel. This brake can be conveniently operated from the outside and can be used to take the whole weight of the revolving part in case the step bearing should fail. In ordinary operation the shoes of the brake will be set about .01 in. below the brake ring to be in position to receive the revolving part in case the step bearing part should fail. Another function of this brake is to stop the machine when it is desired to do so, and it is stated that one of the 5,000-kw vertical machines will run for four or five hours after the steam has been shut off unless load is put upon it or a brake is applied.

The data are given of the test of a 2,000-kw machine operating a 6,600-volt, 25-cycle generator in the General Electric Works at Schenectady at a speed of 750 r.p.m. With a load in kilowatts of 637 and a vacuum of 28.2, the consumption of steam was 20.1 pounds per kw-hour; with a load of 1,000 kw and a vacuum of 28.9 the consumption was 16.3 pounds; with a load of 2,000 kw and a vacuum of 28.3 in., the consumption was 15.3 pounds per kw-hour.

Mr. Francis Hodgkinson contributed a paper entitled "Some Theoretical and Practical Considerations in Steam Turbine Work," which related principally to the Westinghouse-Parsons type of turbine. The paper after a résumé of the fundamental principles of the steam turbine, gives short descriptions of the several types of steam turbines now on the market, and then takes up the description in detail of the Westinghouse-Parsons type. The description, which is the best that has yet appeared of this type of turbine, enters largely into matters of direct practical interest. In explaining why three diameters of a barrel have been generally used in this type of turbine, it is said that this selection has no bearing whatsoever on the theory of the machine, but is merely one of mechanical convenience. The proper expansion can be provided for just as well should there be one or several different diameters. It will be found, however, that if a speed and diameter of a drum were selected that would permit convenient proportions of the blades of the outlet, the blades at the inlet of the turbine would become mechanically small; similarly, if diameters and speeds were selected to suit the inward blades, the areas of the blades in the last stages would become unmanageably large. Referring to the matter of leakage, it is pointed out that in order to avoid overestimating its probable extent, it is necessary to bear in mind a point which is usually lost sight of and which in a considerable measure offsets the loss from this source. This is that since in a machine of given size the radial clearances between the ends of the blades and the walls of the turbine are constant, the greater leakage naturally occurs at the high-pressure ends of the turbine or at the beginning of the expansion; and by the time the lower stages of the turbine have been reached, the total volume of the steam has become so great compared with the clerance area that the latter becomes unimportant. All leakage steam returns energy to the working steam in the form of heat, as its action is similar to wire drawing treating in a restricted opening. Hence, it is superheated in a slight degree and serves to partially dry the working steam, which contains considerable moisture due to adiabatic expansion.

Referring to the early Westinghouse-Parsons turbines of large size which were constructed in tandem, two-cylinder form, it is stated that the two objects of this construction were to reduce the span between bearings and to allow the use of a reheater between the high and low-pressure cylinders. Exhaustive tests have, however, shown that the reheater is of little or no value in increasing the economy of a turbine. Referring to the effect on economy of entrained moisture in the steam, it has been found that the steam consumption is increased to an amount about twice the percentage of moisture in the steam; that is to say, 2 per cent. of moisture will decrease the economy about 4 per cent. While in small sizes of turbines flexible bearings are used consisting of a nest of concentric bronze sleeves with sufficient clearance between them to permit the formation of oil films to act as cushions, such bearings have not been found necessary in the larger sizes of machines, or in fact for any machines running below 1,200 r.p.m. One of the recommendations of the steam turbine is that it makes possible the use of a still further type of electrical generator which, although possessing difficulties in design for adaptation to ordinary engine speed, becomes ideally suited for direct-connection to the turbine. The machine referred to is the induction generator; that is to say, the induction motor run as a generator. While its peculiar electrical characteristics impose limitation upon its general use in power station work, when employed in conjunction with synchronous apparatus such as between alternators, synchronous motors and rotary converters, it becomes peculiarly suitable for the extension of a power system in which the limit of generator capacity has already been reached. When used on a system to which synchronous motors are connected, by overexciting the fields of these latter, the effects can be neutralized of the magnetizing currents required by the induction motor. This is one of the few cases in which the electrical and mechanical conditions concerning generator and prime-mover are almost exactly suited to each other. In general the higher the speed at which the induction generator can be safely operated, the less the material necessary and the smaller the losses, resulting in an extraordinary efficiency and power factor. For example, with a two-pole, 60-cycle induction generator of 500 kw, running at 3,600 r.p.m., the power factor may be brought as high as 98 per cent. or higher at full load, and the total efficiency will be far greater than that of present generating machinery. The paper concludes with an account of tests of Westinghouse-Parsons turbines and information relating to foundations and power plant designs.

Mr. Lionel S. Marshall, of Cambridge, Mass., contributed an interesting paper entitled "The Use of Superheated Steam and Reheaters of Compound Engines of Large Size." This gives the result of a number of tests made during the past five years on several high-speed, two-cylinder compound engines, all built by the same makers and all of the same type. The investigations were made to determine the economy of the engines under different loads both with and without jacketing and reheating. The paper contains reproductions of almost two-score curve sheets and gives the details of the various tests together with their data. The conclusions are that in the case of large size high-speed compound four-valve engines of common proportions, the jacketing of the high-pressure cylinder is of but little avail when moderately superheated steam (100° F. is used). Reheaters are probably a source of loss unless they superheat the receiver steam at least 30° F., and is not fully effective unless it superheats 100° F. Jacketing the low-pressure cylinder is shown to be unnecessary by reference to the steam qualities during expansion in that cylinder, and, therefore, undesirable when the reheating is effective. The effect of admitting moderately superheated steam to both the high-pressure and low-pressure cylinders is to keep the heat consumption per indicated horse-power practically constant throughout a considerable range of loads—from half load to about one-fourth overload.

Mr. William P. Flint, in a paper entitled "Commercial Gas Engine Testing and a Proposed Standard of Comparison," advocates the determination of the available or brake horse-power and not the indicated horse-power, and a basis of comparison depending upon the suction displacement per minute. It is stated that the results of tests of a large number of gas engines using natural gas for fuel have shown that every 345 cu. ft. of suction displacement per minute will give in the neighborhood of 115 maximum brake hp or 100 effective brake hp. Knowing the diameter of cylinder, the stroke, the test speed and the number of charges possible per double revolution, the suction displacement per minute is simply calculated. The result in cubic feet when used as a numerator of a fraction of which 345 is the denominator, gives what is called a reduction factor. Then, having the brake horse-power and the British thermal units of any given test, if these be multiplied by the reduction factor found as above, the result will be the brake horse-power and the British thermal units on a 100-hp basis. By applying in this manner the results of a large number of tests of gas engines, the manufacturer can ascertain the characteristic British thermal units per brake horse-power curve for each size and type, and from these can predict what new sizes should do. Besides enabling an average performance curve to be located with considerable certainty, this 100-hp basis method also lends itself well to the determination of limiting curves between which the performance of any engine may be expected to fall. This is often found very useful in drawing attention to defects in an individual engine and in detecting errors which occasionally may be made in shop tests.

In a paper entitled "The Potential Efficiency of Prime-Movers." Mr. C. V. Kerr designates by this term in the case of water wheels, the ratio between 550 × the brake horse-power developed, and 62.3 × the flow in cubic feet per second × the head in feet; and in the case of steam engines, the ratio of the heat equivalent of a horse-power or 2,545, and the weight of steam per horse-power-hour × the difference between the initial and final total heat in the steam. Tables are included giving the potential efficiency of a large number of types of water wheels and steam engines. In the case of water wheels this efficiency ranges from 68.3 per cent. to 86.8 per cent. in the case of turbine wheels, and from 81 to 91 per cent. in the case of reaction wheels. In the case of reciprocating steam engines, the efficiencies thus calculated from authoritative tests are with few exceptions above 60 per cent., and going as high as 80.5 per cent. in the case of a Schmidt engine tested at Pabienice, Poland, and to 80.2 per cent. in the case of a Snow pumping engine at Indianapolis. For steam turbines the potential efficiency thus determined is considerably lower than for the steam engine, in only two cases going above 70 per cent.; one of these cases being the test of a Westinghouse 1,000-kw unit giving 70.8 per cent., and a Brown-Boveri-Parsons turbo-alternator giving 71.8 per cent. It would appear, however, that in the case of the steam turbine the efficiency is the combined efficiency of the turbine and generator.

Dr. Pupin Before the New York Electrical Society.

The 243d meeting of the Society was held at Havemeyer Hall, Columbia University, May 25. The secretary read the following statement: "On the first of June last year a special meeting was held for the purpose of considering and discussing the revision of the constitution and by-laws of the Society, which had been adopted by the executive committee for report to the 243d meeting of the Society. At that special meeting certain amendments were passed. The legality of the action of this meeting in so passing these amendments was subsequently called into question, and in order to determine its validity the executive committee empowered the president to secure legal advice on the point. I have here the opinion on the same duly rendered by Parker & Aaron. The document, which is somewhat lengthy for present reading, advised the president of the Society that the action of the special meeting in question was not legal, and that he, the president, must not recognize any validity as attached to the attempted amendments. This opinion was submitted to the executive committee at its March 31 meeting, and duly approved and formally adopted by the committee. On the direction of the executive committee, the president subsequently appointed as a committee to revise the constitution and by-laws of the Society three of its past presidents, Francis W. Jones, Gano S. Dunn and Arthur Williams. The report of this committee was duly submitted to the executive committee and approved and adopted by it at its meeting of April 26. The revision, as recommended by the committee and as approved by the executive committee, will now be submitted to the Society. The further action necessary in this case is that this revised edition of the constitution and by-laws shall be further submitted to the Society at its next meeting, at which it shall require a two-thirds vote for its adoption." The revision of the constitution and by-laws, as submitted by the revision committee to the executive committee, and approved by the executive committee, was then read.

The subject of the evening was "Selective Signaling by Electrical Resonance." Dr. M. I. Pupin explained that he had originally intended, according to promise, to lecture to the Society on the "Physics of Wireless Telegraphy," but, owing to absence in Europe and lack of time, he had been unable to prepare an adequate lecture on that subject. The present subject, however, was closely identified with many of the phases of wireless telegraphy, which he had intended to treat in the lecture first proposed. Dr. Pupin proceeded to explain the principles and essential elements of the system of transmission by electrical resonance, classifying these elements as the multi-frequency alternator, the transmitter, the distributors, the resonators and the rectifiers. As described by Dr. Pupin, the alternating-current generator consists of six fields and six armatures, mounted on the same shaft. The various fields and armatures differ from each other in the number of poles. The number of poles is 4, 6, 10, 16, 24 or 34, giving frequencies of from 60 to 512. The various e.m.f's generated by these machines are impressed upon the line by tuned transmitters. At the receiving end there are branch circuits in parallel with each other, each branch consisting of a coiled condenser, so adjusted that the branch will offer a minimum impedance to one of the six frequencies transmitted. In inductive relation with these distributors are local resonators tuned electrically to respond to one of the six frequencies. Each resonator works upon a local relay circuit, this circuit consisting of a relay constructed like a Weston direct-current voltmeter. In series with the relay is a polarization cell, consisting of platinum electrodes in dilute sulphuric acid. In series with the relay is a rectifying polarization cell described by Dr. Pupin in several publications, and patented within the last few years. The polarization cell enables the alternating current to actuate the direct-current relay.

At the special request of the United States Patent Office Commissioner, Dr. Pupin has prepared an exhibit for the United States Patent Office, at the St. Louis Exposition, illustrating the transmission of telegraphic messages by alternating currents of various frequencies, the receiving and transmitting apparatus being electrically tuned to the frequencies, which they are intended to receive and transmit. This exhibit was shown at the lecture, but much to Dr. Pupin's disappointment it was not in working order, owing to an accident which had occurred during the afternoon. The polarization cell anodes had been covered with platinum black and this defect was not discovered until some time after the lecture.

The annual meeting of the Society is to be held in June at the Lamp Testing Bureau, Eightieth Street and East End Avenue, when the regular business of the occasion will be supplemented by some interesting features. A large attendance is expected.

New Telephone Patents.

EXCHANGE SYSTEM.

Just as two-wire common battery switchboards have superseded the three-wire boards in some localities, in the attempt to successfully bring the maximum number of subscribers' lines within the reach of an operator, so is it natural that a one-wire wiring scheme for multiple jacks should be brought forward as a further step in the same direction. At first sight the difficulties to be overcome in designing circuits for such a switchboard seem almost insignificant; but to devise a system to meet the demands of modern operating methods is no mean problem, first because of difficulty in obtaining the desired signals for supervision, and second because of the difficulty of balancing such a system. The first of these difficulties seems to have been rather simply overcome by Mr. C. E. Scribner in a system described in a patent just issued to him and assigned to the Western Electric Company. All relays are associated directly with the various subscriber's lines, the cord circuit containing no signaling apparatus except the ringing keys and supervisory lamps, these latter being included in the talking circuit. Herein would seem to lie a serious disadvantage from the "talking" standpoint, because of the introduction of the lamp terminals into a part of the talking circuit carrying continuous current. This, coupled with cross-talk difficulties, will probably render the system in its present form valueless from a practical standpoint.

LIGHTNING ARRESTER.

In Fig. 1 is shown a very compact and neat arrangement of fuse and open-space cut-out for combined use as a lightning arrester. It

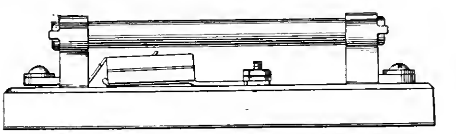

FIG. 1.—BARCLAY LIGHTNING ARRESTER.

is the idea of the inventor, Mr. J. C. Barclay, of New York City, to bring these two devices into as small a space as practicable and yet have either removable for inspection without disturbing the other, and he has certainly succeeded admirably.

SELECTIVE SYSTEM.

Messrs. F. C. Penfield and O. Templin have recently patented a selective system adapted for independently ringing up to ten parties upon a single line. The system depends upon the point use of both sides of the line and the ground in various combinations with relays and selective bells and several sources of current. At two of the stations both relays and bells are responsive to alternating currents, the selection of one of these stations being dependent upon the application of such current to one side of the line only. At these stations the relays are arranged to open the bell circuits when energized, and each is wired through a condenser to ground from the side of the line other than that from which its bell is wired. There-

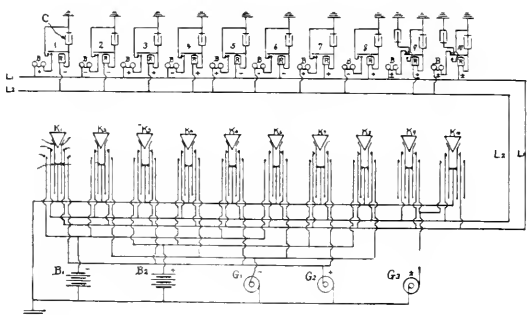

FIG. 2.—PENFIELD AND TEMPLIN SELECTIVE SIGNAL SYSTEM.

fore, when the relay is operated the bell cannot be. For every other station the bells are normally upon open circuit, being grounded only by the actuation of the corresponding relay. Both relays and bells at these stations are polarized and the latter are biased to respond to impulse currents of one sign only. For these stations the relay is normally grounded through a condenser, but it is found that the charging of this latter is sufficient to cause the relay armature to respond sufficiently to automatically short-circuit the condenser as long as the actuating current is maintained. Fig. 2 shows diagrammatically the circuit of this system, the signs indicating clearly the current combinations necessary for the different stations.

AUTOMATIC SYSTEM.

Several years since an automatic exchange system was patented by J. C. Slater, of St. Louis, for which an improvement now appears. The system referred to requires the subscriber calling to insert a pin in a socket corresponding to the desired number, and then to release a rotating arm which, under the influence of a motor, proceeds synchronously with a central office switch arm. Upon the completion of the connection it is necessary to withdraw the above-mentioned plug to restore the apparatus to normal, and it is the subscriber's failure to do this which has led to the present improvement. With the modified apparatus, if the receiver be returned to the hook and the plug not withdrawn, an auxiliary signal bell notifies the subscriber of his error.

CIRCUIT CHANGER.

Under this title a method of bending springs for switchboard keys or hook switch elements has been patented. The peculiarity of these springs is that the flaring of the end is about a line diagonal to the length of the spring, the inclination of this line with the edge of the spring being such as to correspond with the angle from which the actuating plunger approaches. C. C. Cadden, of Cleveland, Ohio, is the inventor, the Williams Abbot Electric Company obtaining the patent by assignment.

Trolley and Steam Developments in New England.

It is stated, from New England sources, that trolley competition, which has seriously affected the profits of steam roads in Central New England, will be met by a reduction of fares by the Boston & Maine Railroad, which is paralleled by trolley roads between Springfield and Greenfield, a distance of 40 miles. The New York, New Haven & Hartford Railroad and the Boston & Albany division of the New York Central Railroad, which are affected by trolley competition, are also considering similar measures.

The schedule of fares which will go into effect on the Connecticut River Division of the Boston & Maine Railroad is in every instance as low as the trolley rates. The railroad has suffered especially heavy loss in local traffic between Springfield and Northampton. Under the new schedule the fare from Springfield to Holyoke, a distance of nine miles, will be reduced from 15 to 10 cents. Between Northampton and Springfield, 18 miles, the fare will be cut from 33 cents to 20. From Springfield to Greenfield the rate will be 50 cents instead of 83. Reductions will be made in about twenty instances. The road provides frequent service, and expects to regain traffic which patronizes the trolleys for economical reasons.

The railroad officials believe that the saving in time and the more comfortable accommodations which steam cars afford in stormy weather will result in a return of the public to the steam cars except for short distances. The action of the railroad comes as an entire surprise. Electric road officials admit that the reduction will hurt their business, as they have no way of checkmating the new schedule except by concessions which would eliminate profits.

The New York, New Haven & Hartford Railroad, which has met trolley competition in parts of Connecticut by obtaining control of the trolley lines, will, it is authoritatively stated, adopt a different method to regain traffic between Hartford and Springfield. The road runs but few trains between the two cities over the Highland and Central New England divisions. These routes, it is said, will be equipped with the third-rail system and cars run at frequent intervals. The fare will be the same as by trolley, with the advantage of greater speed.

The Consolidated Railway Company—the corporate name of the new combination of trolley roads controlled by the New York, New Haven & Hartford Railroad, and including the Fair Haven & Westville, of New Haven; the Worcester & Connecticut Eastern, and the Meriden Electric Railroad—has just been formally organized. Officers were chosen as follows: President, C. S. Mellen; first vice-president, E. H. McHenry; second vice-president, H. M. Kochersperger; secretary, J. G. Parker; treasurer, A. S. May; assistant treasurer, T. F. Paradise.

CURRENT NEWS AND NOTES.

HARD TO GET ELECTRICIANS.—The artillery corps of the Army is, according to the New York *Tribune*, having great difficulty in obtaining master electricians. The place has existed for a year or more, and the War Department has been able to appoint only six who are in all respects qualified. Six others are being trained in the practical discharge of the duties of the place at Fort Totten, N. Y., preliminary to final appointment, but no one has any idea where the remaining thirteen master electricians are to come from. These men receive $75 a month, the highest pay of any of the enlisted force of the military establishment. Their duties are technical, and, as is indicated by the title of the place, relate to electricity in the coast forts. It was expected that civilians would be induced to come into the army, but the restrictions of military life do not seem to attract good electricians from that quarter. So far only two appointments have been made from civil life.

ANOTHER DANGER FROM ELECTRICITY.—The New York *Sun* prints a letter from a Mr. J. S. Daggett, of Saratoga, who brings a new charge against electricity. There are, he says, irrefutable facts at hand proving that the use of electricity has caused during the past fifteen years a greater loss of property by fire, flood, storm and unseasonable weather than the value of ten railroads like the New York Central. "Are our farmers along the northern Atlantic slope to be ruined? Have we an Agricultural Bureau? So intense was the cold during the past winter that the ground was frozen six feet deep. In digging graves gunpowder was used for blasting out. Millions of fruit trees have been killed. Science says that you cannot use electricity as we do without affecting the air, weather and climate. Must the people suffer to gratify the stupidity of certain corporations? A gentleman has just informed me that his orchard of fine trees has been ruined. The roots of the trees are as dead as though burned by fire. New England and New York State did not receive the tenth of a crop of yellow Indian corn last year. The Government should prevent the use of electricity on such a scale as is proposed by the New York Central now. What are the interests of all the railroads and all the manufacturing electricians as compared with the agricultural interests?" Unfortunately, Mr. Daggett does not set forth the "irrefutable facts," nor does he favor us with the source of his scientific inspiration—which would be interesting.

HIGH-SPEED CENTRIFUGAL PUMPS.—Prof. J. E. Denton and Mr. William Kent have recently made some exhaustive tests of a type of centrifugal pump made by the De Laval Steam Turbine Company, especially designed for use with De Laval steam turbines. Three pumps were tested as follows: 1. A single-stage centrifugal pump designed for delivery of 1,700 gallons per minute and a lift of 100 ft. when running at 1,545 r.p.m. This pump was direct-connected to the geared shaft of a 55-hp De Laval steam turbine. 2. A single-stage pump direct-connected to a 20-hp direct-current electric motor, designed for 1,200 gallons per minute against a lift of 45 ft. and at 2,000 r.p.m. 3. A two-stage pump designed for a delivery of 250 gallons at 700 ft. head; the large pump being driven at a speed of 2,205 r.p.m. by direct-connection to the geared shaft of a De Laval steam turbine, and the small pump driven at 20,500 r.p.m. by direct-connection with a high-speed shaft of the engine. The object of the tests was to determine the efficiency of the pumps. The efficiency of the first-mentioned pump was found to range from 74.3 to 75.6 per cent. for delivery between 1,398 and 1,860 gallons per minute, the efficiency representing the ratio of the water horse-power of the pumps to the brake horse-power of the driving motor. The steam per hour brake horse-power running condensing ranged from 24.06 to 20.53 pounds for these deliveries. The test of the electric motor-driven pump showed an efficiency of 71.4 per cent. for a maximum delivery of 1,403 gallons per minute to 75 per cent. for a delivery of 1,133 gallons, falling down to 68.3 per cent. for a maximum delivery of 790 gallons per minute at the highest heat of 59 ft. With throttle suction there was a decreased efficiency of only 2 per cent. The two-stage compound pump showed a consumption of steam per water horse-power-hour ranging from 40.5 pounds for the maximum horse-power and highest head to 106.2 pounds for the maximum delivery, lowest head and lowest horse-power.

LETTER TO THE EDITORS.

The Inventor's Point of View.

To the Editors of Electrical World and Engineer:

SIRS:—The rule in some foreign countries (but not in our kindred Great Britain) requiring the manufacture of an invention within a fixed limit of time is one of the greatest evils ever invented by a government. Former Commissioner of Patents Seymour has eloquently represented this disadvantage, and so have one or two others in reply to your editorial, which was valuable because of the vigorous discussion it is provoking and because of the new way of looking at the subject it brought forward. Besides, the majority may have agreed with you as far as I know.

The rule of three settles the whole question, I think. An invention is either ahead of time or just on time, or a little late. If the first the public will not accept it until they want it. To require manufacture before the public wants it, would be a severe penalty instead of an honor and reward for the inventor. The phonograph is an illustration. The broad patent became seventeen years old and therefore died a natural death before it was used as a popular substitute for the music box. The profits have come in to all except the inventor since the patent expired. Consequently, it is a punishment, financially and morally, to require "working" of inventions in advance of their day or to require several years to perfect sufficiently to be accepted by the public.

Secondly, if the invention "takes" from the start, the working requirement is useless. So also if the invention comes too late, as do many of the bicycle patents that would have brought big prices when the bicycle was popular.

Another manner of viewing the subject is to consider, as the law does, that seventeen years have been decided as a fair limit in absolutely every patent without exception. Now, if a thousand inventors have been thus rewarded, it is nobody's business whether they make $50,000 during the whole period gradually or during the first year, and none afterward, or during the last year and none before. The inventor who made the profit the first year would not be punished by the "working" requirement, whereas the other inventor would have lost his chance. In other words, the requirement would be an evil, because it would be unjust, and that argument points to the fundamental principle of the United States Government—justice to all alike. France and Germany are more arbitrary. It is so often beyond the power of an inventor to create a market for his invention that it would be cruel to try to force him to equip a $10,000 plant and manufacture and offer for sale a device which he knows is not wanted. However, it is possible for him to pay a nominal tax to test his faith in its probable future success, and this tax at the end of the fourth year, as in Great Britain, would not be very objectionable, but yet it would interfere with strict justice. Why should any citizen pay a tax on property that may not at the present amount to ten cents worth, and yet in the course of a few years may sell at sight for a small or large fortune. All real estate is taxed at a small per cent. of what it would bring at the time. All land will sell for something at an auction. Not so with all patents at any one date.

NEW YORK. EDWARD P. THOMPSON.

[Our correspondent appears to lose sight of the fact that a patent monopoly is not granted as a personal reward, but indirectly to encourage national prosperity by directly encouraging invention. Any public monopoly is in itself an evil, to which principle a patent monopoly is not an exception; but balancing good against evil experience in the past has shown that as a rule the good predominates in this particular kind of monopoly, thereby justifying the burden which its erection and enforcement lays on the public. To keep the balance, however, necessitates minimizing the evil; and while rules for safeguarding the public at times may bear hardly on individual inventors, it must be recognized that the other party to the compact —in our country, the sovereign people—have a right to condition its gift of monopoly. Any advantage taken of the monopoly granted which perverts its intention, that is—a final gain to the public—is an [illegible] that calls for suppression even though injury thereby be inflicted in exceptional cases. Unworked patents block the way of development along the lines they cover. and in the case of further and valuable invention along these lines, the original patentee can come forward and appropriate from the later inventor the fruits of his labor. But the greatest abuse in this connection is in the steady growth of the "paper" and "defensive" patent practice. which violates the fundamental principles justifying the grant of a patent monopoly, since the existence of such patents acts to restrict invention and places on the public a burden with no mitigating advantages to justify its imposition. Undoubtedly. when introducing into the constitution the principle of the patent monopoly. and subsequently in patent legislation. the lawgivers have had uppermost in mind the inventive genius represented by Watt as a type on the one hand, and on the other hand the devoted investigator and ingenious shop worker; and to-day we venture to say that the great mass of the American public consider that our patent system is erected and maintained for the encouragement of these types. In point of fact, however, except in the case of some great fundamental invention, the isolated, typical inventor is yearly becoming placed at greater and greater disadvantage, both within the Patent Office, where he has to meet "defensive" patents and "feeler" applications, and subsequently owing to the narrowing of the market for the patents of "outside" inventors.—Eds.]

DIGEST
OF
Current Electrical Literature.

Dynamos, Motors and Transformers.

Vertical Motor-Generator Groups.—A fully illustrated description of six motor-generators installed for an Austrian aluminum company. Their axles are arranged vertically, the commutators being about 5 ft. above the ground. The reason for this arrangement is that the various direct-current generators installed by the same company are also arranged with vertical axles coupled to vertical turbines. The attendants are well acquainted with this arrangement, which has proven very satisfactory since the care of the brushes is simpler and easier. The motors are built for 1,000 hp at a voltage of 1,000 and a frequency of 45, while the direct-current generators give 560 kw at 160 volts. The cast-iron magnetic field of every direct-current generator rests on the ground and on it the armature of the three-phase motor is directly placed. The two rotors are directly connected together. The dimensions of the machine are given with some curves of tests and detailed drawings.—*Zeit. f. Elek.*, March; (Potsdam), April 16.

References.

Construction of a Three-Phase Synchronizer.—Percy.—An article with dimension drawings on a useful synchronism indicator which may be produced by properly combining two small transformers, three incandescent lamps and a set of connecting lugs and sockets of the type commonly used for connecting up synchronizing lamps. One of the transformers must be three-phase and the other single-phase. The outfit is described in detail.—*Am. Elec.*, May.

Magnetic Stray Fields in Induction Motors.—Guilbert.—The first part of a long mathematical article with reference to a recent paper of Behn-Eschenburg, on this subject.—*L'Eclairage Elec.*, May 13.

Lights and Lighting.

Street Lighting by Nernst Lamps.—Joseph.—An article in which the author endeavors to show that under favorable conditions, with the use of Nernst lamps, it is possible to produce a better light than that given by incandescent gas mantles, at a smaller annual cost per lamp than is charged in most towns for gas lighting, and still show a small net profit, which, together with the improved load factor, will show a marked increase in the profits of the undertaking. He first endeavors to "slay the frequent renewals bogey," and then gives tables of cost.—Lond. *Elec. Rev.*, May 13.

Arc Between Mercury and Carbon.—Cassudo.—An account of tests of an arc between mercury and carbon. For the same current and the same distance of the electrodes, the voltage at the electrodes of the arc is greater if mercury is cathode and carbon anode, than if mercury is anode. The sum of the anode drop of voltage and the cathode drop of voltage is about the same for both directions of the current, but the drop in the column of the arc is greater if mercury is cathode than if it is anode.—*Phys. Zeit.*, May 15.

Power.

Electrically-Driven Rolling Mills.—Köttgen.—A long paper illustrated by diagrams in which the author first discusses merchant mills. Small mills, with motors from 300 [illegible] hp, have been in operation for several years, and that they have given satisfaction is evinced by the fact that five larger mills ranging from 1,000 up to 1,500 hp are now being arranged for electric driving. Motors for mill driving must be susceptible to two kinds of regulation: first, it must be possible to set them for a normal speed, acording to the desired circumferential speed of the rolls; secondly, they must slow down considerably as the load increases, in order that the energy stored in the fly-wheel may be utilized. This regulation is accomplished by various means. With direct current a compound winding is provided and the regulation is effected without any appreciable loss of efficiency. On the other hand, with alternating current it is necessary to introduce resistance in the armature; this is a course of loss which, however, remains comparatively small until the speed is materially reduced. The economy of such a motor depends upon the duration of the decreased speed. The problem of balancing the power needed is of great importance, in order that both dynamo and motor may be protected, and it is usually solved by heavy fly-wheels. The use of a motor-generator makes possible a simple method of regulating the speed of the mill by coupling direct to the shaft of the same a generator for each and every driving motor and raising or lowering its voltage by the shunt. This also obviates the necessity for a starter, as the driving motors can be started by lowering the voltage in the primaries. In most cases the use of either fly-wheel or battery will be unnecessary. The author then compares the relative advantages of electric driving and the use of gas engines coupled direct to the mill. The introduction of electric transmission from the power station (which is equipped with gas engines) will add to the first cost, but on the other hand larger and, therefore, less expensive engine units are used; moreover, since all mills will not be using their maximum power simultaneously, the capacity of the power house can be measured by the average of the power needed. Another great advantage is the facility which motor driving offers for measurement of the power used, affording a continuous control, not only over the condition of the mill, but also over the roll design. This will tend to a lower consumption of power and an improvement in quality of the product. He then discusses the electric driving or roll tables and finally takes up the subject of reversing mills. In designing the electric drive for a blooming mill there are two important points: first, the mechanism to be employed for starting and stopping, since reversing gears cannot be used for such powers; secondly, the balancing of the variations in load since variations which may exceed 6,000 hp cannot be carried by the generating station. Both problems are satisfactorily solved by Ilgner's system, hitherto mainly used for mine-hoisting engines. It consists of installing between generating station and motor a motor-generator set coupled to a very heavy fly-wheel. The dynamo of the set is always built for direct current and the mill is driven direct from the latter, and by simply regulating the small shunt current the voltage of the so-called starting dynamo is raised or lowered. If it is raised the speed of the mill motor increases; if lowered, electric breaking takes place because the motor is forced to decrease its speed, and thereby transmit energy through the dynamo into the attached fly-wheel. This interposed motor-generator not only obviates the necessity of a starting resistance and permits electric braking, but also keeps the large variations in load in the secondary system away from the primary station and circuits. Variations in load are carried by the fly-wheel.—*Iron Age*, May 19.

Power Station Design.—Merz and McLellan.—The conclusion of their paper on power station design. They deal with the switch gear and emphasize that, on account of the absolute crippling of the power station which takes place, if there be any serious failure of the switch gear, it is justifiable to take every protection even at the expense of capital expenditure. Oil switches are essential and all high-tension circuits should be broken in this way—if only for the reason that opening the circuit under oil puts so much less stress on the cables and on insulation generally. The switch chosen should be capable of breaking any current which may be met with in practice. This practically means, in emergency, breaking the whole short-circuit capacity of the station. One of the greatest dangers to reliability of supply is the excessive carelessness with which cables connecting machines or feeders to the switchboard have in the past been cramped together indiscriminately in a trench or tunnel. In the case of a power station it is unsafe to allow cables carrying large powers, whether high or low-tension, even spaced some inches apart in tunnels or manholes, unless each cable is in its own duct or in some other way protected from the properly earthed metal shield. All instruments should be worked through transformers. Automatic overload devices should be installed so as to operate the switches on each outgoing feeder. The automatic adjustable circuit-breakers should have a time lag inversely proportional to the magnitude of the overload. The authors add some remarks on measuring apparatus and records and urge that complete permanent apparatus should be provided for the taking of necessary tests, thus avoiding the unreliability and uncertainty of make-shift arrangements.—Lond. *Elec.*, May 13.

Superheated Steam.—SMITH.—An article on the thermal effect and the practical utility of superheated steam. He endeavors to show that its utility has no reason beyond that of keeping the engine cylinder walls, piston surfaces and valve seats and faces dry. This dryness is of immense utility. While superheating gives a thermodynamic advantage beyond the maintenance of dryness, yet it is so very slight as not at all to compensate the expense of the process. The practical conclusion is that superheating should be carried only to that degree sufficient to insure dryness.—Lond. *Elec. Rev.*, May 13.

British Power Station.—A fully illustrated description of the Central Electric Supply Company's power station which supplies current "in bulk" to the Westminster electric supply corporation and St. James & Pall Mall Electric Light Company. The three-phase system has been adopted at 6,000 volts with a frequency of 46. The output last year was over 2,600,000 kw-hours. The price charged was 6 cents per unit, and a much lower price will be charged during the current year. The most striking features of the station are the use of Climax boilers only, without economizers, and the absence of condensers and superheaters.—Lond. *Elec. Rev.*, May 6 and 13.

Cheap Supply "in Bulk."—The Hull municipal electric plant intends to offer to the Northeastern Railway for lighting and power purposes 1,000,000 kw-hours per year at 2½ cents per kw-hour on a basis of a 27 per cent. load factor. This figure of 2½ cents will be liable to an increment or decrement of ⅛ cent for each three per cent. decrease or increase in load factor.—Lond. *Elec.*, May 13.

REFERENCES.

Steam Engine Speed Regulation.—MCGUIRE.—An illustrated article treating of the perquisites of engine governors. After briefly explaining the general purposes which a governor is required to subserve, the author enumerates the advantages and disadvantages of the two principal classes, namely, those that throttle the steam and those that vary the point of cut off.—*Am. Elec.*, May.

The Zeuner Valve Diagram.—MAJOR.—An illustrrated description of the Zeuner valve diagram and explaining its utility in solving problems relating to valve gears.—*Am. Elec.*, May.

TRACTION.

Mountain Railroad.—ARMKNECHT.—The first part of an illustrated article of the mountain road to Hohensyburg in Westphalia, Germany. It is partly an adhesion road and partly a cable road. The length of the latter is 445 meters and the gauge one meter, the difference of level being 93 meters. While one car is going down, another is going up. The greatest tension in the cable occurs when the car going upwards and filled with passengers enters the heaviest grade. The greatest power is required from the motor when at the same time the car going downwards is on the place of smallest grade and carries no passengers. The greatest tension of the cable is 2,929 kg. For operating the cable two motors are provided, one of which is in action while the other is used as reserve. Both motors have a capacity of 72 hp and are shunt-wound, direct-current motors running at 390 to 410 revolutions at a voltage of 500 volts. The connections of the motors are shown in Fig. 1. In order to start one of the motors the switch, *J*, is closed by hand and the rheostat, *R* and R^1, are adjusted. Their levers are mechanically connected in such a way that the resistances of the armature circuit are not dis-

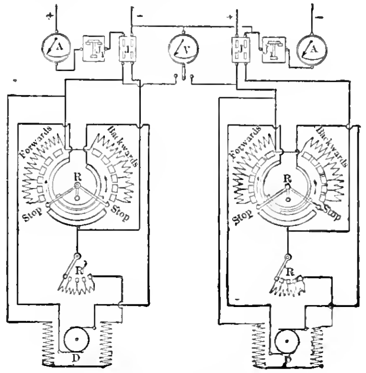

FIG. 1.—MOTOR CONNECTIONS.

connected before the exciting circuit has been closed. The attendant is thus able to send current into the armature only after the normal intensity of the magnetic field has been reached. The direction of rotation is determined by revolving the lever to the left or the right. In the circuit of each motor an automatic circuit-breaker, J_1, is inserted which is set into operation as soon as the current reaches a dangerous value. It is thus prevented that the current in the armature can get a dangerously high value, when the brake is actuated before the motor is disconnected.—*Elek. Zeit.*, May 12.

Interurban Railway Operation.—HERRICK.—A discussion of the new problems that have been brought on by the development of interurban lines from city systems. The author believes that the trolley is ill suited for heavy current collection at high speeds and that considerable improvement is possible in the present third-rail system. He suggests that the collector shoes be placed on the roof of the car and current collected from a light third rail placed on supports at a height of 2.5 meters above the surface of the road and far enough on the side to prevent accidents to passengers. He also states that the wires used on interurban cars are generally too small, as they are usually figured on the mean current taken by the motors, and that much trouble with motors and controllers is due to the fact that the voltage on the line near sub-stations is sometimes as high as 700 to 780 volts, whereas the equipment is designed for a 550 to 650-volt service. After taking up the question of multiple-unit control, distribution of feeders, and the danger of placing curves at the bottom of heavy grades, the author refers to electromagnetic signal systems and states that while ideal in theory they do not work out so well in practice, the reason being that the speed at which these magnets are required to work does not allow sufficient time to saturate the armatures, and if wound to operate when the car is running at a certain high speed they will be burned out if the same energy is applied if the car should happen to stand over a signal point. He suggests that where two trolley wires are used, each insulated from the other, a system of cut-outs can be devised so that when the car is taking current from one trolley wire the connection between the other and the feeder will be open, thus making head-on collisions between signaling points impossible.—*St. R'y Jour.*, May 21.

Rail Bonding.—SHEARDOWN.—The conclusion of his paper on tramway rails and rail bonding. He considers that the Falk system of cast welding has undoubtedly been a success in the United States; it was employed between 1896 and 1900, but since then the process has been apparently more or less ousted by the electric welding process. One of the drawbacks to the continued commercial success of the cast-welded joint appears to be the size of the equipment required and the fact that it came expensive unless a large number of joints could be poured at one time, which often proved to be inconvenient. The electric conductivity appears to be good, better than the usual allowance of copper bond. The welding process is quoted as a good example of the determination with which Americans will extend energy, time and money on any new process which they believe can be made a commercial success. The development of the electric welding process is briefly sketched. The thermit system of welding is "a most interesting process and one which would appear to have a great future before it, not only for the welding on street rails. In some of its other applications it is practically without a rival." Several rail joints made by this process are under test on their latest extension on the Drumcondra line and so far appear to have satisfied expectations. The conductivity of a length of rail with the joint appeared as good and in some cases better than a similar length of rail without joint.—Lond. *Elec.*, May 13.

Single-Phase Traction.—A note stating that Dawson, as a witness before the Royal Commission on London Traffic, recently advocated the use of single-phase alternating-current motors for suburban railways, with reference to the motors of Finzi and Lamme and to the great advantage of a 2,000 to 3,000 trolley wire. There will be no longer any necessity for the third rail with its cumbrous and dangerous fittings at ground level, while step-down and step-up transformers with rotary converters will be abandoned. With a single-phase system, the conductor is cheap to install, so that a trial can be made on a selected section of line without great expense and with very little disturbance of general traffic. Since we are not yet within sight of the electric driving of long-distance trains, any system to be adopted must permit of the continuous use of the locomotive on the same lines as the electric trains. Nothing lends itself to this so easily as the trolley wire.—Lond. *Eng'ing*, May 13.

REFERENCES.

High-Speed Railroads.—Peterson.—The conclusion of his article on railroads running at a speed as high as 200 km. per hour. He discusses the track and rail construction and arrives at a result that the obtainable speed is limited in first line by the degree of exactness to which the rails can be maintained true in position, and only in the second line by the strength of the track construction. He considers the single-rail suspended road as the most suitable one and recommends that further trials should be made.—*Elek. Bahnen*, No. 9, May.

Saint Louis.—An article on some features of the East St. Louis & Suburban Railway, directly opposite St. Louis. One of the two lines leading to Belleville is used almost entirely for hauling coal from the coal mines nearby. The city lines in East St. Louis are operated directly from direct-current generators, but the rest of the system is fed by sub-stations which receive alternating current transmitted at 13,000 volts. The transmission wires are of aluminum.—*St. R'y Jour.*, May 14.

Hanover.—Liebenberg.—A fully illustrated description of the new trolley system of Hanover. Accumulator traction was formerly used on this system, but the following disadvantages were found very troublesome: danger due to explosion of gases developed in the accumulators, no reliability of prompt service, the trouble and the expense of the attendance of the batteries. The trolley system has now been introduced and the system is described at great detail.—*Elek. Zeit.*, May 5.

New York Central.—An editorial discussion of the reasons for the use of electric locomotives for through trains on the New York Central Railroad within a zone in which the suburban trains will be operated by electricity. This zone is 34½ miles long on one division and 21 miles on another division. The use of electricity was required by law for only a short section, about 3½ miles in length. The discussion to use electricity for the entire distance is commended.—*St. R'y Jour.*, May 14.

Scarborough.—An illustrated description of the Scarborough electric tramways which use the trolley system. The power plant contains two 300-kw steam turbines.—Lond. *Elec. Times*, May 12.

Train Testing.—Ashe.—A description of the instruments used and the methods followed in making a series of train tests. A number of curves are presented showing speed, voltage, amperes, kilowatts, acceleration and distance.—*St. R'y Jour.*, May 21.

Installations, Systems and Appliances.

Charging for Electric Energy.—Schoenborn.—An article in which the author says that the theoretically most correct and most fair systems of charging for electrical energy can be introduced into practice only with great simplifications and have remained so imperfect that only very few plants have introduced them. If one abandons the idea of accomplishing what really is impossible, he thinks there are only left two systems which are practical: the double tariff and the tariff based of the hours of consumption. The latter tariff is based on the consideration that a consumer of electric light who uses 600 hours is more favorable than if he uses the light for only 300 hours, since in the former case he will consume some energy during the hours of relatively low load. This tariff, if supplied to lighting only, is, therefore, apt to flatten the peak of the load curve and make it broader. The same system, however, has not the same effect if applied to energy for power purposes. For the use of power the double tariff seems more advantageous. Fig. 2 shows the action of the two

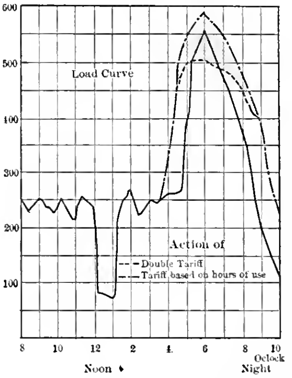

FIG. 2.—CHARGING FOR ENERGY.

systems on the load curve for a lighting system only. If one takes into account the cost of introduction of one of these systems into a plant which has not formerly used it, the general introduction of the tariff based on the hours of use is cheap and the introduction of the double tariff is expensive, because the meters so far used have to be removed and new meters must be installed. A small cost is involved in the introduction of the tariff based on the hours of use for lighting only and of the double tariff for power; in this case the meters for measuring power which are to be replaced by double tariff meters can be installed for new light consumers.—*Elek. Zeit.*, May 12.

REFERENCES.

Switchboard for Tramway Station.—A fully illustrated description of the switchboard for the London County Council tramway power house. It is on the "remote control" system which has been used in several plants in this country and is now being introduced in England.—Lond. *Elec.*, May 13.

Non-Arcing Lightning Arrester.—A description of a lightning arrester in which the discharge is led through a combination of carbon and mica plates having intervening air-gaps, the result being that the static discharge is broken up into infintesimal sparks and conducted to the ground.—*St. R'y Jour.*, May 14.

Electro-Physics and Magnetism.

Structure of Atom.—Nagaoka.—A mathematical paper on the "kinetics of a system of particles illustrating the line and the band spectrum and the phenomena of radioactivity." His model consists of a large number of particles of equal mass arranged in a circle at equal angular intervals and repelling each other with forces inversely proportional to the square of distance; at the center of the circle a particle of large mass is placed attracting the other particles according to the same law of force. If these repelling particles revolving with nearly the same velocity about the attracting center, the system will generally remain stable, for small disturbances, providing the attracting forces be sufficiently great. The system differs from the Saturian system, considered by Maxwell, in having repelling particles instead of attracting satellites. The model is approximately realized if these satellites are replaced by negative electrons, and the attracted center by a positively charged particle (this model differs from that recently described by J. J. Thomson, in so far as Thomson's uniformly electrified sphere is replaced by a positively charged particle in the center). This model is applied to a mathematical investigation of the line and bond spectrum and the author thinks that various other problems will possibly be capable of being attacked on the same hypothesis, such as chemical affinity and valency, electrolysis and other subjects connected with atoms and molecules. —*Phil. Mag.*, May.

Thomson Effect in Alloys of Bismuth and Tin.—LAWS.—An account of experiments which show a striking effect of the addition of a very small amount of tin to bismuth, the Thomson effect in the alloy containing 1 per cent. tin being more than twelve times as much as in pure bismuth. With the addition of more tin the value of the Thomson effect continues to increase until the alloy contains about 3 per cent. of tin when the effect is about fifteen times as much as for bismuth. When the percentage of tin is increased beyond this amount, the value of the specific heat of electricity begins to decrease and this diminution goes as the amount of tin becomes greater, until finally the Thomson effect in the case of pure tin has fallen to a value which is only about 1/300 part of that which holds in the case of bismuth.—*Phil. Mag.*, May.

Resistivity of Mercury.—GUILLAME.—A note referring to the elaborate tests of Smith on the variation of the resistivity, *R*, of mercury with temperature, *t*. Smith gives the following equation:

$$Rt = R_0\ (1 + 0.00088036\ t + 0.0000010309\ t^2).$$

The author formerly found the following equation to hold true:

$$Rt = R_0\ (1 + 0.00088090\ t + 0.0000009986\ t^2).$$

Both formulas are nearly the same, but the author thinks that his own formula is a little more exact.—*L'Ind. Elec.*, May 10.

Influence of Radium on the Electric Spark.—A note on experiments of Stefanini and Magri, who found that for discharges between two spheres, or between a positively charged point or sphere and a negative disc, the discharge is facilitated by radium for short sparking distances and impeded for longer ones. If the disc is positive and the sphere or point negative, the discharge is impeded at small sparking distances within a limited interval; in general the effect is nil. For certain sparking distances between a sphere and disc it is possible for radium to impede or facilitate discharge according to which electrode is positive.—Lond. *Elec.*, May 6.

Power Factor.—An illustrated didactic article treating of combined capacity and inductance and power factor.—*Am. Elec.*, May.

ELECTRO-CHEMISTRY AND BATTERIES.

Osmotic Pressure.—SEBOR.—An account of an investigation of the speed of diffusion of water through a semi-permeable diaphragm. The speed of diffusion is approximately directly proportional to the osmotic pressure of the dissolved substance. It seems possible to determine from the speed of diffusion the osmotic pressure and the molecular weight of the dissolved substance.—*Zeit. f. Elektrochemie*, May 13.

REFERENCES.

Electrolysis of Sulphites.—FRIESSNER.—An extended investigation of the electrolysis of sulphites. If neutral or alkaline sulphite of sodium or potassium is electrolyzed, the anodic reaction is the oxidation of the sulphite to sulphate and under certain conditions dithionate may be formed. The latter formation may be compared with persulphate and percarbonate formation. The conditions under which it takes place are investigated in detail.—*Zeit. f. Elektrochemie*, April 22.

Electrochemistry.—IZART.—A concise review of the present condition of the various electrochemical industries in the world.—*L'Ind. Elec.*, May 10.

Concentration of Hydrogen Ions.—SALM.—A paper on the possibility of determining the concentration of the hydrogen ions in a solution with the aid of indicators.—*Zeit. f. Elektrochemie*, May 13.

UNITS, MEASUREMENTS AND INSTRUMENTS.

System of Units.—EVERETT.—A communication on the completion of the practical system of units, with reference to recent suggestions of Robertson. The proposed changes involve the selection of units of mass, length, time and magnetic permeability that will give the ohm, volt, etc., without the introduction of arbitrary multipliers. This is accomplished by using the kilogram and meter as fundamental units and employing a unit of permeability 10^7 times the permeability of vacuum, and the permeability of vacuum equal to 10^{-7}. Secondly, it is suggested to so alter the units of permeability and permittivity as to make Heaviside's "rational" formulas applicable. The permittivity of vacuum then becomes $\frac{1}{36\pi} 10^{-9}$ and the permeability of vacuum $\frac{1}{4\pi} 10^{-7}$. When the rational values of permitivity and permeability are employed in conjunction with the kilogram, meter and second, the capacity of a condenser is area divided by thickness multiplied by permitivity; and the induction within a long helix carrying a current is ampere-turns per unit length multiplied by permeability. When the units used as fundamental are coulomb, meter, kilogram, second, there are fractional exponents in the dimensions of the electrical and magnetic units, and he inclines to the adoption of the coulomb rather than the ohm, because a specified number of grams of silver is a more matter-of-fact thing than a resistance. Moreover, it does not vary with temperature as a materialized resistance does. For kilogram he suggests the name kilog and for meter the abbreviation met.—Lond. *Elec.*, May 13.

Measuring the Phase Difference of Three-Phase Generators.—BAUCH.—In generator tests it is important to determine exactly the phase difference between the current and voltage. For this purpose the watts are measured with the wattmeter and voltage and current with a voltmeter and ammeter, respectively. This measurement may involve a considerable error, especially if the generator is star-connected, for the reason that the star voltage may have a wave form considerably different from the tension between the terminals. This is possible because the former may contain harmonics of the third order, which need not occur in the tension between the terminals. The author investigates mathematically how far it is possible with the usual methods of measuring to determine correctly the watts and the phase difference. Several connections are discussed for measuring the phase difference for different conditions of wave form and load. The author shows that there exists no means for measuring accuracy the wattless component of the current for inductive load by means of only one watt, current and voltage measurement.—*Zeit. f. Elek. u. Masch.* (Potsdam), April 16.

Utilizing Old Day Batteries.—HANCHETT.—A short article giving a few uses to which old dry batteries may be put in testing. The common expedient to obtain low voltage when only a high-voltage circuit is available, is to connect the circuit to be supplied in multiple with a suitable resistance which is connected in series with the line. This resistance is not always easy to obtain, and aside from being inconvenient, is a source of heat and requires more current from the line than is used in the derived circuit. A very convenient means of eliminating this difficulty is to use a sufficient number of dry battery cells in place of the resistance, selecting such a number as will give an open-circuit voltage equal to the desired voltage at the work circuit. If the apparatus is so arranged there will be practically no current flowing through the dry cells when the work circuit is closed, so that the dry cells will not be a source of heat or trouble and also have the advantage of being very compact and a convenient substitute for the resistance and one easy to secure. In the case of a three-wire system, where the neutral is grounded, a bell circuit might be supplied in shunt to a set of dry cells connected in series with a lamp circuit which was continuously alive and on the side next to the neutral wire. If the current in this lamp circuit is kept down to a reasonable amount, it is probable that very little trouble will be experienced in the battery in a number of years. The greatest value of the battery "resistance" is its convenience as a laboratory expedient. —*Am. Elec.*, May.

REFERENCES.

Alternating-Current Integrating Wattmeter.—An illustrated description of the Brush-Gutmann integrating wattmeter for alternating currents. It is of the induction motor type. The readings which are direct in watt-hours are stated to be true within 2 per cent. from the starting load to 50 per cent. overload for meters up to 50 amp. and in larger sizes within 3 per cent. from starting to 25 per cent. overload. Temperature changes are said to have no effect from 40 to 120° F. The construction of the meter is described. —Lond. *Elec.*, May 6.

Reichsanstalt.—An abstract of a long official report of the work of the German Reichsanstalt from the beginning of 1900 to the end of 1903. Since the account is very concise, it cannot well be abstracted.—*Elek. Zeit.*, May 12.

TELEGRAPHY, TELEPHONY AND SIGNALS.

Four-Party Selective Ringing System.—O'BRIEN.—An illustrated description of the Leich system. Two instruments are connected to each side of the line and at the central office two generators are provided which furnish current at different frequencies. There are two types of instrument used with the system, the difference between them being entirely in the arrangement of the ringing circuit. Each type of instrument is equipped with a 1,000-ohm ringer, a retardation coil and a condenser. The circuit arrangement of this apparatus, however, differs materially in the two cases. In operating one of the two different sources of ringing current at the central office furnishes 60-cycle current and the other furnishes 20-cycle current. The division of the instruments into two types is due to the fact that one is designed to respond to a ringing current of low frequency while the other is intended for a high-frequency current. In the former instrument a two-microfarad condenser and a 2,000-ohm retardation coil are connected in series with a 1,000-ohm ringer, the free terminal of which is grounded. With this arrangement, the impedance of the ringing circuit for the low-frequency instrument will increase directly as the frequency of the ringing current increases, so that a point may be reached where the frequency of the ringing current has become so high and the impedance of the circuit so great that sufficient current cannot pass through the ringer to actuate it. With the high-frequency instrument, the arrangement of the ringing circuit consists in connecting a 0.3-microfarad condenser in series with a 1,000-ohm ringer, the free terminal of which is grounded, and bridging the ringer with a 1,000-ohm retardation coil. The action of a condenser in an alternating-current circuit is directly opposite to that of a retardation coil. The impedance offered to the flow of the alternating current by a condenser varies inversely with the frequency of the current, so that with the high-frequency instrument the impedance offered to a 60-cycle current is considerably less than that offered to the 20-cycle current. The particular impedance coil used with this system is designed so that its impedance may be varied to suit unusual line or switchboard conditions. For this purpose the core of the coil is made up of a number of E-shaped annealed iron punchings which can be readily inserted or withdrawn so as to adjust the impedance of the coil. Instruments equipped with this type of selective apparatus have been successfully operated over lines up to ten miles in length, without any adjustment whatever.—*Am. Elec.*, May.

Train Dispatching.—A description is given of the telephone dispatching system used by the Rochester & Eastern Rapid Railway Company. The dispatching line consists of a pair of copper wires carried on porcelain insulators on brackets below the high and low-tension feed wires. At switches and other convenient points jack boxes are fastened to the poles and connected by water-proof wires to the telephone line. Where connection is desired in emergencies and no pole box is near, a connecting hook pole is used, the bottom of which contains a socket into which the telephone plug can be inserted. —*St. R'y Jour.*, May 21.

Independent Telephone Development in the Northeast.—An illustrated description of the automatic telephone exchange of the Northeastern Telephone Company at Portland, Me. The underground system and aerial lines are sufficient to accommodate 5,000 subscribers on outside construction, and the ultimate exchange capacity will be for 10,000 subscribers; 2,500 automatic switches are already installed in the exchange and the full capacity limit for the switches already installed is expected to be reached during the year. The company has now 250 miles of rural pole line construction with about 175 miles of trunk line connecting between 60 and 70 towns, villages and cities in northeastern Maine, with 12 exchanges and 75 to 80 pay stations outside of Portland. It connects with several rural and farmer lines covering territory adjacent to the company's main lines. It is also under its licensee company's management, the Lewiston-Auburn Telephone Company, preparing to build an exchange for those two cities connecting by trunk line with the company's main exchange in Portland, 35 miles away.—*Am. Elec.*, May.

New Books.

RUBBER, GUTTA-PERCHA AND BALATA. By Franz Clouth. New York: D. Van Nostrand Co. 242 pages, illustrated. Price, $5.

This is an English version of the original German treatise, known for many years past to students of the subject treated. Good judgment has been shown in making the translation and in adding a quantity of new material. In each instance of the three substances the author deals with its history, habitat, properties, methods of handling in refinement, and commercial uses of the manufactured product. Unfortunately, there is no index, but the chapter contents give a summary of topics. We can heartily commend this work to all our readers—and they are not a few—specially interested in the important problems of electrical insulation.

ANWENDUNG UND ZUKNFT DER KONDENSATOREN IN DER WECHSELSTROMTECHNIK. By W. Von Bisicz. Berlin: Julius Springer. 88 pages, 26 illustrations. Price, 3 marks.

This is a compendium of quantitative information concerning condensers in alternating-current distribution circuits. The applications of condensers in telegraphy and telephony are not considered. The leading formulæ controlling condenser currents and pressures are clearly given and the bibliographical references are very numerous. In fact, the main value of the book lies in the copiousness of its references.

The book is divided into seven chapters. The first is introductory. The second and third deal with condensers in series and in parallel respectively. The fourth and fifth deal with particular arrangements of condensers. The sixth and seventh relate to practical considerations concerning the use of condensers.

It is shown, among other things, that the cost of a condenser varies directly as the capacity and as nearly the square of the impressed voltage. That is to say, the cost varies approximately as the energy storage capacity. The book is useful as a reference index for electrical engeineering students interested in condensers.

CYANID PROZESSE. Zur Goldgewinnung. By Manuel von Uslar and Dr. Georg Erlwein. Halle: Wilhelm Knapp. 100 pages, 32 illustrations. Price, 4 marks.

This is the seventh volume of the well-known German serial of monographs on applied chemistry. It gives a review of the cyanide processes for gold production and deals both with zinc precipitation and with electrolytic precipitation. The first chapter gives a description of the McArthur-Forrest and the Siemens & Halske processes. The second chapter contains examples from practice with cost sheets. In the third chapter the author discusses the chemical reactions during solution and during precipitation and in the fourth chapter he gives a review of the various modifications of the original McArthur-Forrest and Siemens & Halske processes, which have either been proposed or introduced into practice.

The compilation is well done and the statements and descriptions are concise and clear. The various processes which have been proposed are critically discussed, and the book appears to give complete information on the cyanide process up to about 1900 or 1901. In a later edition the more recent developments—and especially the interesting combination of electrolytic with zinc precipitation, due to Charles Butters—should be considered.

AMERICAN METER PRACTICE. By Lyman C. Reed. New York: McGraw Publishing Company. 196 pages, 78 illustrations. Price, $2.

Since substantially all electrical energy sold is measured by some form of meter, the subject of metering is one of much importance. Its literature, however, is surprisingly meagre, Mr Reed's book being almost the first on the subject. Great literary merit would perhaps be too much to expect in an extremely practical treatise by a busy "meterman" such as the author. A prominent editor, being asked whence came his remarkable facility of expression, replied "that is not as easy as it looks: I rewrite everything four times." The first chapter of "American Meter Practice" did not, apparently, receive sufficient revision, for some errors contained are evidently due to carelessness rather than to unfamiliarity with the subject. The intended meaning will, however, be obvious to the central station "meterman," for whose instruction the book seems to be especially written.

The chapter on meter selection is very satisfactory and that on torque and friction is especially so, due, perhaps, to its having benefited from the revision and criticism incident to previous publication in the technical press. The passing of the chemical meter is appropriately noted, and its successor, the "motormeter," in its various makes, is discussed at some length, but not exhaustively. Chapter XII on records and testing is perhaps more indicative of individual than general practice. With the avowed purpose of enabling the non-technical consumer of electric energy not only to read his meter but roughly to check its accuracy, full directions are given for so doing. On page 169 it is stated that the average meter underregistration causes a 15 per cent. loss of revenue to the supply company. This figure is, however, wide of the mark in the case of cities where the more modern bearings, friction compensating appliances, testing methods, etc., are employed. Differential rating is interestingly discussed, and the book closes with an excellent chapter on photometry, which is evidently "thrown in for good measure," as it is not covered by the title of the book. Persons engaged in the electric light and power industry will find the book as a whole especially valuable.

BOOKS RECEIVED.

THE THEORY OF THE LEAD ACCUMULATOR. By Dr. Friedrich Dolezalek. Translated from the German by Dr. Carl L. von Ende. New York: John Wiley & Sons. 241 pages, 30 illustrations. Price, $2.50.

N. E. L. A. International Congress Delegates.

Three papers will be presented at the International Electrical Congress at St. Louis on behalf of the National Electric Light Association, as follows: "American Practice in High-Tension Line Construction and Operation," by Dr. F. Eastman, Chicago.

New York Central Electric Locomotives.

In our issue of May 21 we presented a review of the reasons that may be taken as those which have influenced the New York Central & Hudson River Railroad Company in adopting electric traction

The new electric locomotives which are being built for the New York Central & Hudson River Railroad Company at Schenectady, by the General Electric Company and the American Locomotive Company, differ radically in their electrical features from any electric locomotive hitherto constructed. The motors are bipolar gearless, the magnetic circuit, the field windings and the motor poles being integral with the locomotive frame and spring supported. The pole faces, which are laminated, are vertically tangential to the armature, thus providing for vertical movement of the locomotive frame with attached poles without affecting the armature air-gap. The armature is assembled on a quill which is pressed solidly on the axle. The dual weight of the assembled rotating part, including the armature, axle and wheels, is less than on many steam locomotives, and there being no uncompensated reciprocating parts there is a perfect rotative balance.

This design was submitted in accordance with specifications prepared by the Electric Traction Commission appointed by the railroad company, the members of which are Messrs. William J. Wilgus, fifth vice-president New York Central & Hudson River Railroad; John F. Deems, general superintendent of motive power of the railroad company; Bion J. Arnold, Frank J. Sprague and George Gibbs. The secretary to this commission is Mr. Edwin B. Katte, electrical engineer of the railroad company. This commission, after careful deliberation, had prescribed the conditions which must be fulfilled by electric locomotives taking the place of steam locomotives as far as Croton on the Hudson River line and as far as North White Plains on the Harlem Division, a distance of 34 miles and 24 miles respectively.

These conditions were, briefly, that the successful bidder should furnish an electric locomotive capable of making two regular successive trips of one hour each between Grand Central Station and Croton with a total train weight of 550 tons, a single stop in each direction, and a lay-over not to exceed twenty minutes. In addition to this it was provided that a similar schedule should be maintained with somewhat lighter trains making more frequent stops. Finally, it was provided that with a total train weight of 435 tons, the electric locomotive should be able to run from Grand Central Station to Croton without stop in forty-four minutes, and, with one hour lay-over, be able to keep up this service continuously. This last schedule is the equivalent of the present timing of the Empire State Express, though the latter has a somewhat lighter train.

Specifications embodying these conditions were prepared by the commission and sent to all the principal electrical manufacturing companies both here and abroad. It will be observed that no restriction was placed on bidders as to whether direct or alternating current was to be used. The successful bidders were the General

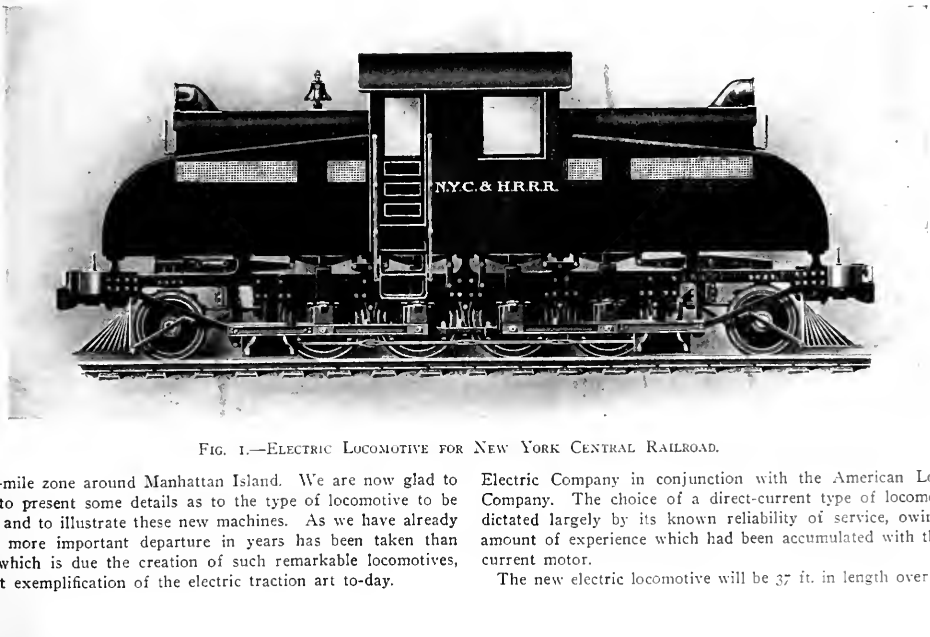

FIG. 1.—ELECTRIC LOCOMOTIVE FOR NEW YORK CENTRAL RAILROAD.

for a 40-mile zone around Manhattan Island. We are now glad to be able to present some details as to the type of locomotive to be adopted, and to illustrate these new machines. As we have already said, no more important departure in years has been taken than that to which is due the creation of such remarkable locomotives, the finest exemplification of the electric traction art to-day.

Electric Company in conjunction with the American Locomotive Company. The choice of a direct-current type of locomotive was dictated largely by its known reliability of service, owing to the amount of experience which had been accumulated with the direct-current motor.

The new electric locomotive will be 37 ft. in length over all. The wheel base will consist of four pairs of motor wheels and two pairs of pony truck wheels, the length of the total wheel base being 27 ft., and of the rigid wheel base consisting of the four pairs of motor wheels 13 ft. The diameter of the driving wheels will be 44 in. and of the truck wheels 36 in. The driving axles will be 8½ in. in diameter. It will be what is known as a double-ender and will weigh approximately 190,000 pounds.

The frame is of cast steel, the side and end frames being bolted together at machined surfaces and stiffened by cast-steel cross transoms. The journal boxes and axles are designed to permit sufficient lateral play to enable the locomotive to pass easily around curves of 230 ft. radius.

The superstructure of the locomotive is to be of steeple form so designed as to offer the least practicable wind resistance consistent with the adequate housing of the apparatus and its convenient operation. The cab is designed so as to afford a clear view of the track. The whole of the superstructure is to be of sheet steel with angle iron framing, and the doors and windows of the cab are to be fireproof.

The driving power of the locomotive is furnished by four 600-volt, direct-current, gearless motors, each of 550 hp. This will make the normal rating of the locomotive 2,200 hp with a maximum rating of about 2,800 hp, or about 50 per cent. greater than that of the largest steam passenger locomotives now in service. The armatures are mounted directly on the axles and will be centered between the

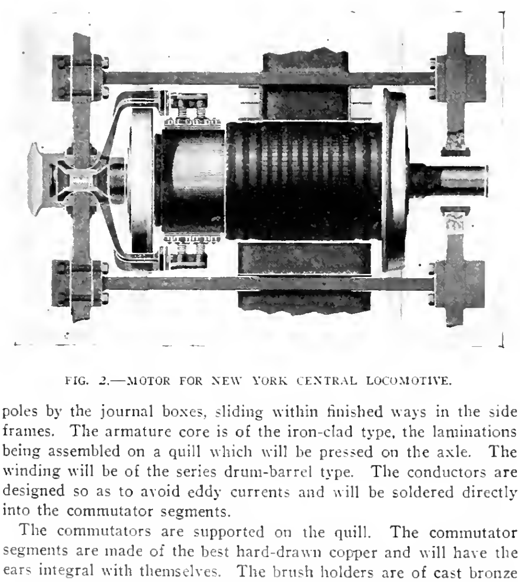

FIG. 2.—MOTOR FOR NEW YORK CENTRAL LOCOMOTIVE.

poles by the journal boxes, sliding within finished ways in the side frames. The armature core is of the iron-clad type, the laminations being assembled on a quill which will be pressed on the axle. The winding will be of the series drum-barrel type. The conductors are designed so as to avoid eddy currents and will be soldered directly into the commutator segments.

The commutators are supported on the quill. The commutator segments are made of the best hard-drawn copper and will have the ears integral with themselves. The brush holders are of cast bronze and mounted on insulated supports attached to the spring saddle over the journal, maintaining a fixed position of the brush holder in relation to the commutator.

Unlike the ordinary four-pole motor where the magnetic circuit is made through a separate box casting, the magnetic circuits in this type of electric locomotive are completed through the side and end frames. The pole pieces are cast in the end frames and there are also double-pole pieces between the armatures carried by bars which act as part of the magnetic circuit. The pole pieces are shaped so that the armature is free to move between them with ample clearance on the sides. As the poles move up and down with the riding of the frame on the springs, they will always clear the armature and provision is made so that the armature will not strike the pole pieces even if the springs are broken. The field coils will be wound on metal spools bolted to the pole pieces and will consist of flat copper ribbon.

The Sprague-General Electric multiple-unit control is to be used on this type of electric locomotive. There are two master controllers in the cab so placed that the operating engineer looking ahead will always have one of these under his hand. The control system permits two or three locomotives to be coupled together in any order in which they happen to come and to be operated as one unit by the engineer in the leading cab.

The control system is also semi-automatic in its action, as it provides check on the rate of acceleration of the train, which the engineer cannot exceed, while he may accelerate at any slower rate if he so desires. Should two locomotives break apart, the control current will be automatically and instantly cut off from the second locomotive without affecting the ability of the engineer in charge to control the front locomotive under his charge. The control system is designed for a minimum of 300 volts and a maximum of 750 volts.

The weight which rests upon each of the driving wheels of the electric locomotive will be about 17,000 pounds, proper distribution and division of the weight among axles being accomplished by swinging the main frames from a system of elliptical springs and equalizing levers of forged steel, the whole being so arranged as to cross equalize the lead and furnish three points of support. The locomotive is provided with all the usual accessories of a steam locomotive, including an electric air compressor to furnish air for the brakes, it will have whistles, a bell and an electro-pneumatic sanding device and electric headlights at each end. The interior of the cab will also be heated by electric coils.

In actual performance this locomotive is expected to give better results than any engine hitherto placed upon rails. With a light train the locomotive is expected to give speeds up to 75 miles an hour, and with heavier trains similar speeds can be attained by coupling two locomotives together and working them as a single unit. Its tractive force will be greater than that of any passenger locomotive now in existence, and it is believed that in the simplicity and accessibility of its parts and in the provision made in its design to insure continuous operation with the minimum chances of failure, that it marks an entirely new and successful type of electric locomotive.

A New Slip Meter.

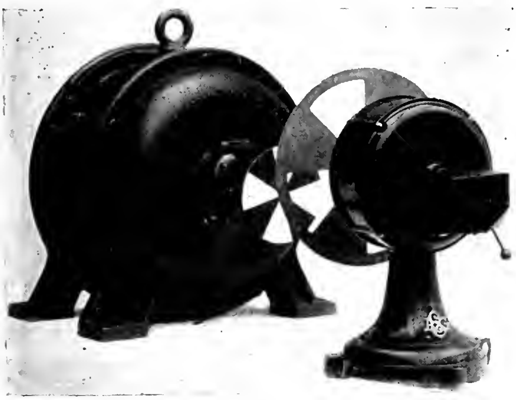
By Franz Welz.

At a recent meeting of the German Institute of Electrical Engineers, Mr. G. Benischke, chief electrician of the Allgemeine Elektrizitäts-Gesellschaft, gave a description of his new apparatus for measuring the slip of induction motors. This effect is determined by the formula, $s = \frac{n_1 - n_2}{n_1}$, where n_1 is the number of revolutions of the rotating field and n_2 the number of revolutions of the rotor. As the difference between these two values is generally very small, the correct determination of the slip is quite difficult, and small errors in taking the above-mentioned values affect the result very largely. Mr. Benischke had, therefore, indicated a method which allows a direct reading of the difference, $n_1 - n_2$, in making use of the so-called stroboscopic effect well known in physics.

According to this method, the shaft of the rotor is provided with a disc which is divided in several black and white segments. This disc is lighted by an arc lamp, which is fed through the same distribution system as the induction motor. The number of passages of these segments before a fixed point in a certain time allows the determination of the difference $n_1 - n_2$. But in addition it is still necessary to know the number of cycles of the current, or the number of revolutions of the generator. In many cases it is not advisable to use an arc lamp on the circuit, as it results in an unequal distribution of current in the three phases on account of its high amperages. In using an incandescent lamp, this stroboscopic effect is only visible in a darkened room.

From this method Mr. Benischke has developed a very simple apparatus which permits the determination of the slip in a convenient and absolutely accurate manner. No light source is necessary, nor is a record of the time to be made; neither does it require a special instrument for determining the number of revolutions. The apparatus (see illustration) consists of a small three-phase synchronous motor, which is self-starting and reaches synchronism very quickly. A disc, from which a number of segments is cut out, is attached at one end of the shaft and on the other end there is a counter, driven by rack and pinion, which can be thrown in and out by a little lever. A stroboscopic disc is attached by means of wax to the shaft of the induction motor to be tested. This disc consists of black and white segments of the same number as on the disc on the synchronous motor. The latter motor is put at a certain distance from the induction motor, and if both are running and the observer looks through the disc of the synchronous motor upon the other disc, the segments seem to rotate. The number of passages before a fixed point can be counted very easily, and this gives the difference $u_1 - u_2$; the number of revolutions of the rotating field, u_1, is given simultaneously by the counter. The value of the formula above given is not dependent on the time, and it is, therefore, of no importance for which period of time the values $u_1 - u_2$ and u_1 are taken; the only condition is that only values taken at the same time are to be compared. It is, therefore, not necessary, as in the case of the method of illuminating the disc or with other methods of counting the pulsations of current in the rotor, to record simultaneously the time, all that is necessary being to count the numbers of passages of the segments and read from the counter of the synchronous motor the number of revolutions during that time. The quotient of the first value by the latter gives the slip of the motor.

The simplest arrangement is that in which the disc of the synchronous motor and that of the induction motor have the same number of segments, and it is best to use for this number the number of poles of the induction motor to be tested. In order to get actually



SLIP METER.

the difference $u_1 - u_2$, it is necessary to divide the observed number of passages of the segments by the number of the segments on the disc of the induction motor. If the slip is very large, the segments turn too quickly to make it possible to count the number conveniently. In this case it is best to employ a disc with only one segment; the observed number of passages is then equal to the number of "slipped" revolutions. This involves another advantage compared with the method of counting the number of pulsations of current in the rotor. These pulsations follow each other so quickly in the case of a large slip (commencing at about 0.06) that they cannot be counted with any accuracy; with this new apparatus the number of slipped revolutions can be counted directly by employing discs with only one segment. In order to obtain good results it is necessary to place the synchronous motor at a greater distance from the induction motor than is shown in the illustration, as the stroboscopic effect is better visible in proportion as the distance increases.

Long Scale Portable Instruments.

Electrical engineers who employ the portable standard instruments in general use for the making of exact measurements of electrical quantities or in the conduct of tests, know how difficult it is to take accurate observations in those portions of the scale where the divisions are narrow, and the consequent uncertainty regarding results and difficulty in checking up a series of measurements taken with different instruments. The fact that only a portion of the scale is accurately legible and that it is not always possible to have at hand instruments of the proper range to cover all capacities properly, make it at times impossible to avoid the use of comparatively illegible divisions, and as a result the curve sheets of tests and tables of measurements show irregularities which rob the work of all value.

To obviate such troubles and the other embarrassments resulting from the use of imperfect standards, the Department of Standards of the Westinghouse Electric & Manufacturing Company has designed the portable instruments illustrated herewith. The assortment comprises voltmeters, ammeters and single-phase and polyphase wattmeters. Their principal characteristics are convenience in use, permanence of calibration, accuracy and mechanical excellence.

As shown by the illustration, the voltmeter is zero-reading, this form having been found most suitable for measurements for which

FIG. 1.—PORTABLE VOLTMETER.

a voltmeter is used. In this form the readings are determined by the deflection of the milled head required to bring the index pointer to zero. Each instrument is made in two capacities, which in connection with the very long, open scale enables the readings to be

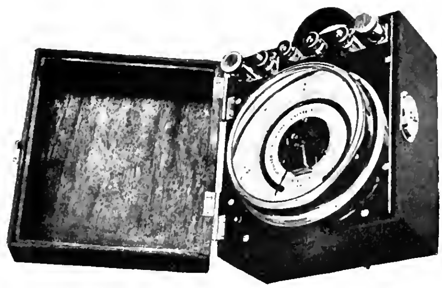


FIG. 2.—PORTABLE AMMETER.

taken over a wide range of voltage with great accuracy. It is astatic and, therefore, unaffected by external fields, and may be used on either alternating or direct currents without a change in calibra-

FIG. 3.—SINGLE-PHASE PORTABLE WATTMETER.

tion and without requiring "reverse" readings to be taken on the latter. It is regularly made in capacities up to 600 volts, but may be furnished for any higher range desired by the use of a multiplier. The action is entirely dead-beat.

The ammeter is similar in external appearance to the voltmeter, with the exception of the terminals, which are designed for the use of heavier connecting wires, and the absence of the knurled head with its indicating pointer, this instrument reading direct. It is furnished with coils wound in two sections, which, by means of small connectors on the top, may be connected in series or in parallel, thus greatly increasing the range of the instruments. The scale is very long and open, being similar to the voltmeter in this respect.

This instrument can be used on alternating currents only, but it is accurate over a very long range of frequencies and may be used on circuits varying from 3,000 to 8,000 alternations without appreciable error. It is also unaffected by changes of wave form on the circuit. The moving element is extremely light and being dead-beat will accurately follow any variation of current.

In the wattmeters the scheme of subdividing the coils as adopted for the ammeters is carried out for both the series and potential windings, thus giving in one instrument four ranges in capacity. In addition to this, as the scales are uniformly spaced from zero to maximum, readings may be taken at any point with equal accuracy, so that one instrument will give a range several times that of any other heretofore obtainable.

The wattmeters are suitable for use with alternating currents

FIG. 4.—POLYPHASE PORTABLE WATTMETER.

only, but like the ammeters, they may be used over a considerable range of frequency. The polyphase instrument consists of two single-phase mechanisms connected to one shaft, and indicating on a single dial the sum of the forces of the two mechanisms. It may be used for either two-phase or three-phase circuits and will indicate correctly the total energy of a polyphase circuit irrespective of power factor or any unbalancing of the different phases. As they are not affected by external fields or proximity to large masses of iron they afford a very convenient medium for making tests of polyphase motors or other devices of this nature under actual service conditions.

Some "Sarco" Specialties.

There is a tendency in this age of great and large achievement to ignore the smaller things, and yet it is the little inventions which often contribute more to the comfort of the human race and in the greater number of instances make it possible for the artisan and mechanic to do his work better. In the field of electrical apparatus these things have been peculiarly noticeable, the inventions which are handled every day by thousands receiving but small attention. It is along the lines of improving the electrical apparatus of every day use, especially that devoted to electric lighting, that the Sarco Company, of 906 Sixth Avenue, New York, has devoted its attention. All of its specialties have distinctly novel features, and include the "Noscru" bell push button, the parabolic aluminum reflector and the "Sarco" outlet boxes. Coupled with these are novelties in the nature of "Key-arm" switches. The "Sarco" two-light aluminum reflector is also of particular interest to those using incandescent lamps and wishing an increased light in two directions.

As a practical novelty the "Noscru" midget bell push button overcomes a difficulty with which those putting in electric bells have been confronted. As its name may be considered to imply, the wires are connected without screws. The face of the button has an appearance similar to those now on the market, being manufactured in the same size with celluloid and pearl centers; but the bottom of the button is one solid piece of hard rubber, two holes running horizontally through the rubber. The button is connected by simply threading two circuit wires through these horizontal holes and bending over the extended ends flat against the piece at the bottom, there being a projecting ridge of rubber to separate the wires. The method of contact is by a yielding plunger that makes direct scraping contact on the circuit wires themselves. These buttons can be connected in ten seconds, and they are readily taken apart for engraving and stamping, by unbending the two pins that are bent over on the bottom of the button. Dampness cannot affect the "Noscru" push button, since the contacts are enclosed entirely in rubber. It is made in various sizes, the smallest called the "Pee Wee" fitting a ⅜-in. hole, and having the advantage of being screwless, is perhaps the only solution to the practical working of a button of this size. Since these buttons, as well as key-arm switches, which are somewhat of the same type, all make direct contact on the wires, they cannot short-circuit or ground.

The "Sarco" parabolic aluminum reflectors can be applied to a lamp without regard to socket receptacle or "Fielding" receptacle, the lamp fitting perfectly into either. This enables a window or frame to be wired with regular fielding receptacles, and by having the "Sarco" reflector applied direct to the lamp, an even better reflecting power is acquired than by using an expensive mirror trough reflector. By its peculiar shell shape it gains at once in power of reflection. The deep-cone type of reflector brings the polished surface of the aluminum so close to the lamp that it is claimed an actual test with an 8-cp lamp will show as much light as an ordinary 16-cp lamp without the reflector. Like the "Noscru" button, simplicity is the keynote of this reflector's construction and it can be applied without shade holder wherever desired, as in factory lighting, show rooms and for large space. Being also of aluminum it has the advantage of being so light in weight that it adapts itself readily to the purposes of almost any kind of a desk lamp or portable. The finish of the reflectors is solid smooth green enamel, resembling in position a green sea shell. The styles manufactured give either a direct reflection or a wide diffusion of illumination, as desired.

The "Sarco" two-light reflector gives another effect in lighting. By applying it to an 8-cp incandescent lamp it is claimed the value of the light is twice multiplied. As the reflector is held part way down the lamp it gives a reflecting power to the light from the lamp and yet at the same time permits the lamp to light the space

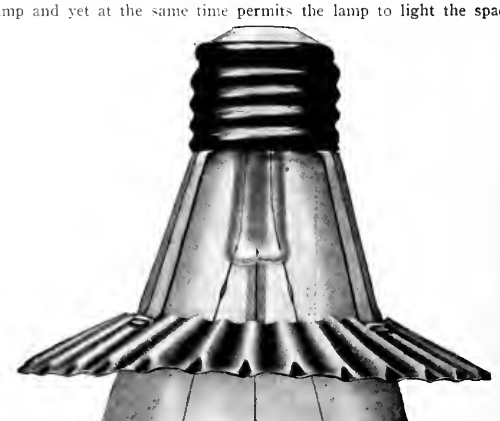

FIG. 1.—2-LIGHT ALUMINUM REFLECTOR.

around it. It is so fixed upon the lamp that it does not in any way interfere with the radiation of the light from all sides of the filament. The two-light reflector is also of polished aluminum and because of its novel construction can be placed inside the ordinary glass shade, thereby increasing the light of the lamp without casting a shadow.

By adapting the "Noscru" principle the "Sarco" company makes a canopy switch which is a real novelty and an entire bracket can be controlled by simply boring a 5/16-in. hole in the canopy, putting the

FIG. 2.—CANOPY SWITCH.

canopy switch in position, then fastening the nut tight, pushing the two wires through the holes and bending them over and replacing the cap—an operation that can be accomplished in ten seconds. Another

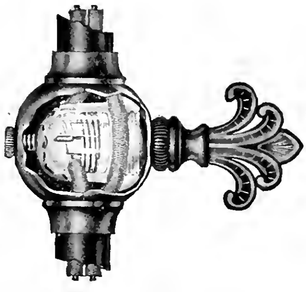

FIG. 3.—"NOSCRU" KEY-ARM SWITCH.

variation of the same idea is in the "Noscru" key-arm switch, which is claimed to be the smallest key-arm switch in the world, it being only one inch in diameter. This key-arm switch instantly makes direct contact on the wires and cannot short-circuit or ground, as all of the working parts are surrounded by porcelain, and underwriters approve nothing else.

Another of the Sarco specialties is known as a "Cast-iron Cinch" in the form of an outlet box. This box was specially designed to meet the latest requirements of the National Code rules, and takes a minimum of time to install as well as exemplifies the best class of workmanship. Styles are made for use with armored cable, and in addition it can be used as a junction box, in every way giving adequate satisfaction.

Fort Wayne Series Alternating Street Arc Lighting System.

The Fort Wayne series alternating-current system of street arc lighting consists in common with other alternating series arc lighting systems of a combination of a constant-current regulator and a number of arc lamps connected in series. The system includes the use of a Wood regulator mechanically different from any others on the market, and form "C" Wood arc lamps specially designed for this service.

The automatic regulator consists of an E-shaped laminated iron core and a reactance coil surrounding the center leg of the core. The coil and core are hung on levers supported on knife edges in such manner that they counterbalance each other, both being movable. The levers are so arranged that the coil moves over the greater portion of the distance, being required to lift the core only through a short distance.

The regulator coil is connected in series with the arc lamp circuit. The regulation is automatic, any change in the resistance of the arc lamp circuit tending to produce a corresponding change in the current in the circuit, since the line voltage remains constant. But any change in the current changes the relative position of the core and coil, an increasing current bringing them closer together, a decreasing current allowing them to move further apart.

As the core enters the coil when they approach each other due to an increase in current, the additional reactance caused by the magnetic condition thus created serves to counteract the decreasing resistance of the line and creates such an impedance that the current remains constant. Any decrease in the load tends to increase the current and draws the coil and core together, thus increasing the impedance in the circuit; while any increase in the load tends to decrease the current and allows the core and coil to separate, thus decreasing the impedance in the circuit. The result is that the current is maintained at its normal value automatically. So perfect are the mechanical construction and electrical proportions of the regulator that the load may be reduced gradually from full load to no load until the regulator is directly across the line in short-circuit without causing any marked change in the current. The load may also be changed from full load to short-circuit with but momentary current variation. This insures perfect protection to the system

FIG. 1.—REGULATOR.

against short-circuits due to failure of insulation of the outside lighting circuit.

When this regulator is intended for use on a small system of 25 lights or less, the lighting system may be connected directly to the machine circuit without the use of transformers. When, however, it is necessary to install the system on a machine supplying other circuits, a transformer is recommended. This transformer is connected between the machine and the series arc regulator circuit, thus insuring perfect separation of its circuit from any others supplied from the same machine. Transformers for this use are furnished of one-to-one ratio, or if higher voltages are required with the proper ratio to obtain the desired voltage for the arc circuit.

It is frequently necessary in installing arc lighting systems to consider extensions of the system to meet the growth of the community. The Fort Wayne series alternating system is designed to take care of extensions and at the same time to operate efficiently with the initial load. This is done by installing a regulator large enough to meet the maximum future demands and a transformer furnishing proper voltage to economically operate the regulator with this partial initial load. This lower voltage is obtained from a series of secondary taps, by means of which the arc circuit voltage may be varied

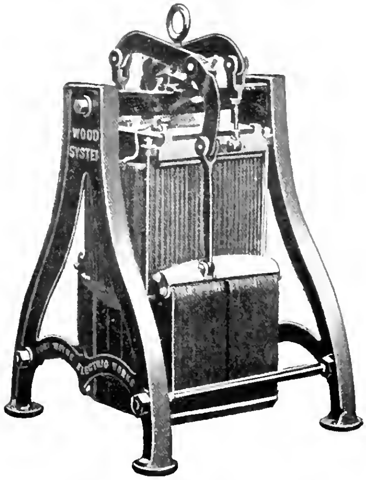

FIG. 2.—REGULATOR.

from 50 per cent. of full voltage up to maximum secondary voltage in steps of such value that the circuit will always be working at approximately full load efficiency. This method of transformation will allow a lighting plant to practically double its series arc lighting output without any increase in the regulating system or transformer, simply by changing the connections on the secondary taps of the transformer; and at all times it insures the highest economy and maximum power factor in the regulator circuit.

Figs. 1 and 2 show the Wood regulator mounted on a stand for station installation. The knife edges are mounted on a casting supported on two A-frames, between which the regulator is suspended. The joints in the levers furnish means for adjusting the regulator for the proper current.

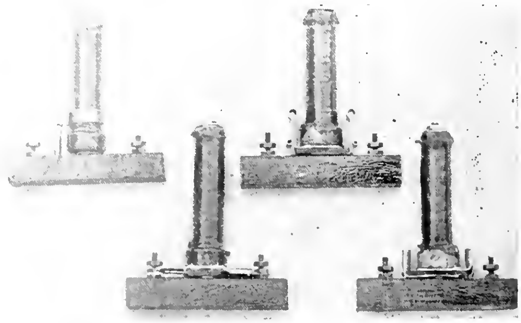
Gas Power Plant Extension.

A gas engine power plant which has attracted considerable notice within the last few years is that of the Union Switch & Signal Company, Swissvale, Pa. This plant at present contains 500 brake hp in Westinghouse three-cylinder vertical gas engines of the direct-connected type. The generators are of 220 volts, alternating current, and operate in parallel upon a common bus, with a widely fluctuating load due to manufacturing operations in the works of the company, for which power is furnished by the plant.

On account of the successful operation of the gas engine plant up to the present time, the Union Switch & Signal Company has decided to increase its capacity, and for that purpose has contracted with the Westinghouse Machine Company for a 300-hp horizontal double-acting engine of the type introduced in 1902 by the Westinghouse Machine Company. It has two cylinders 16½ in. in diameter, 24-in. stroke, arranged in tandem with single crank. The engine will drive a 210-kw Westinghouse alternator which will operate in parallel with the four generators now installed and furnishing 220-volt, two-phase, 60-cycle current for power and lighting throughout the works. The unit, which operates at the speed of 180 r.p.m., has an extended shaft for the reception of a pulley driving a small exciter generator. When the new plant is completed steam will be entirely dispensed with except for heating buildings and running steam hammers and riveters.

Interchangeable Enamel Resistance Units.

As there has been a considerable demand for enamelled resistance units so arranged that they can be conveniently mounted upon panels, switchboards, etc., being so designed that they are readily interchangeable, the Ward Leonard Electric Company, of Bronxville, New York, has designed and perfected the method of mounting

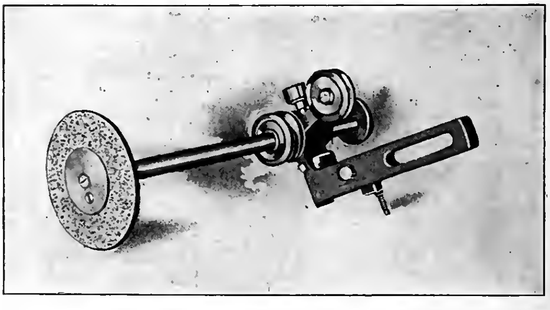


INTERCHANGEABLE RESISTANCES.

shown in the cut. The cut shows B size unit, but any of its different sized tubes can be arranged in the same manner. The tubes can be taken from the bases by hand without use of any tools—just as readily as panel cartridge fuses are removed. Different units of greater or lesser resistance can be used to replace each other and any desired result may be obtained. The Ward Leonard Company has sold over 2,000,000 of its enamelled resistance tubes (having the resistance wire hermetically sealed from the atmosphere) during the last four years, and its engineers, are busy daily accommodating the trade with various improved methods of mounting these devices.

Truing Commutators.

How best and easiest to true up commutators is always a problem for the manager of a plant, and it is universally recognized that the most desirable and proper way is to do it without removing the



DEVICE FOR TRUING COMMUTATORS.

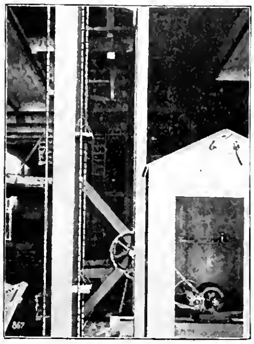
armature from the dynamo or motor needing attention. The device here shown is, as will be seen, very simple, and can be applied to the average machine without any trouble or difficulty. Its use avoids the necessity of removing the armature and placing it in the lathe, and also obviates the danger due to the use of diamond point tools, by digging into a commutator already in bad shape. When the work is done, the commutator is smooth and true. The apparatus is made by Jordan Bros., of 74 Beekman Street, New York City.

Massachusetts Technology at Niagara.

The Western alumni of Massachusetts Institute of Technology will go by special train to their great reunion at Boston this month and a visit to the electrical industries at Niagara Falls is to be given a day of the time en route.

Motor-Driven Contractor's Hoist.

As an indication of the economy of electric motor drive in industries temporary in character and also the adaptability of Northern direct-current apparatus the illustration below is of interest. The equipment shown was installed by a contractor in a metropolitan city, to do away with the cost of installing steam hoisting for the transportation of material required in finishing a building. The cost of current for this work, in this instance, was 50 cents per day, as against a charge of $2.50 to $3.00 per day wages for an engineer for



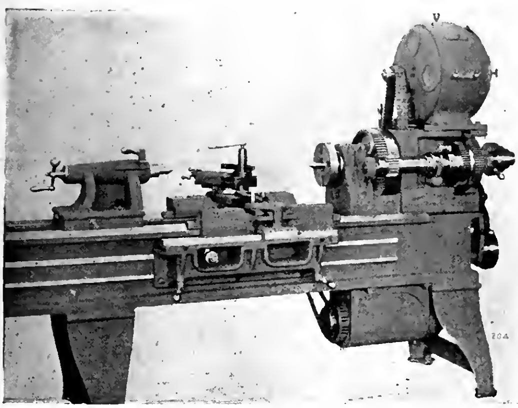
TEMPORARY ELECTRIC HOIST.

a steam hoist, as well as the cost of several hundred pounds of coal consumed each day by the steam equipment.

The motor used is a Northern back-geared motor built by the Northern Electrical Manufacturing Company, Madison, Wis. It is especially adapted to service of this nature owing to its great simplicity as well as rugged and simple character. The motor is a self-contained mechanism, the design and construction of which insures that motors operate with constant alignment of countershaft with armature pinion, thereby securing practically noiseless operation.

Motor-Driven 18-Inch Lathe.

While a great deal has been published recently illustrating and describing motor drives applied to standard machine tools, constant progress is being made in the designing of new tools to accommodate motor drives and in the modification of old tools for the same purpose. One of these latter instances is illustrated herewith, showing an 18-in. Le Blond screw-cutting lathe driven by a shunt-wound



MOTOR-DRIVEN LATHE.

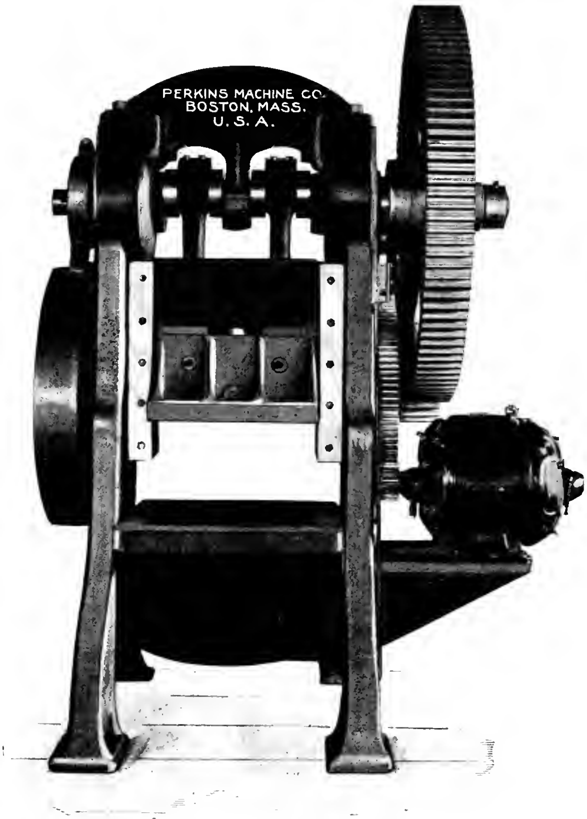
Crocker-Wheeler motor. The motor is supported on a special housing and the drive is by means of a Morse silent chain from the motor shaft to the main lathe spindle. The speed control is accomplished by the multiple system of the Crocker-Wheeler Company, using in this case a controller giving a range of twenty-one speeds. Only a portion of this range is used as working speeds, the entire range of the tool being increased by a double back-gear attachment which permits a total speed range of from 410 r.p.m. of the spindle to 5.75 r.p.m.

With this entire range three runs of gearing are provided, one being direct and the other two through back gears. Each of these various runs is controlled by a friction clutch, the lever for operating which is located in front of the head stock. About 40 speeds are provided with 2.8 hp, available at any speed between 20 and 410 r.p.m. of the spindle. For the heaviest working range of the tool, however, namely, 28 to 124 r.p.m., 3.4 hp is available.

The whole equipment is well laid out, the speed changes are accomplished quickly and easily, and the strength of the motor and gearing is sufficient to accommodate cutting speeds in cast iron and soft steel of 70 ft. per minute. One prominent feature of the Crocker-Wheeler multiple-voltage system is that it affords speeds to use these high cutting speeds properly, and gives ample power at all speeds without an excessively large motor.

Electrically-Driven Machine Tools.

One of the machine tools built recently by the Perkins Machine Company, of Warren, Mass., for the United States Government is herewith illustrated. It is driven by a fully enclosed 10-hp General Electric motor. The machine weighs 18,000 pounds, and has an 8-in.



MOTOR-DRIVEN PRESS.

main shaft bearing. The gear is 60 in. in diameter and weighs 1,800 pounds. Its teeth are cut in the solid metal. The adjustment of the pitmans is very accurate; and by simply turning an internal gear both pitmans are operated at the same time.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—The stock market was exceedingly dull and trading was conducted on a very restricted basis, although there was a moderately firm tone. There were no features of importance, but the steadiness of the bond list and the demand for investment securities attracted attention. The United States Steel issues held firm at a moderate decline, notwithstanding the unfavorable reports of the iron trade. In the traction list Brooklyn Rapid Transit developed strength on favorable reports as to earnings and summer business outlook. Reports continue of the settlement of the litigation between the Amalgamated Copper Company and the Heinze interest, but the manipulation of the former was not of a very confident character. The industrial list as a whole was very quiet. Allis-Chalmers common closed at 7, being a net gain of 1 point; General Electric at 156, a gain of 1 point and Westinghouse Common 156, a net loss of ⅛ point. In the traction list Brooklyn Rapid Transit closed at 47½, a gain of 1½ point, and Metropolitan Street Railway at 110, a loss of 1 point. Western Union is off ¼ point, closing at 87. The curb market was very dull, and the volume of transactions was much decreased. Following are the closing quotations of May 31:

MONTREAL LIGHT, HEAT AND POWER.—The annual statement of the Montreal Light, Heat and Power Company will show gross earnings for the year to be $2,589,000, as compared with $1,937,000 for the previous twelve months. The net revenue after deducting interest on bonds, fixed charges, and a large sum to make good the washing away of the dam at Chambly, amounts to $900,000, or 5¼ per cent. on the capital stock. The bonded indebtedness of this company, nearly $17,000,000, and bearing interest at the rate of 4½ per cent. and 5 per cent. is largely owned in New York and Boston. President H. S. Holt, in his annual report, says: "The increase in net profits for the year amounted to $165,346, notwithstanding the fact that in the gas department there was paid $61,000 additional for coal used, also an increase in wages in both gas and electrical departments of 20 per cent. There were issued during the year $16,000,000 5 per cent. bonds to pay for construction and redemption of bonds of subsidiary companies. The increase in the output of gas was 52,005,000 cubic feet (6 per cent.). The increase of shareholders amounted to 50 per cent."

LOCKPORT, N. Y., POWER ENTERPRISE.—It is reported that the Niagara, Lockport and Ontario Power Company, which is building the canal power from the Niagara River, will also submit a contract to the city to furnish Lockport with water at two cents per thousand gallons. The company agrees to deliver water by 1906. The low rate is offered to give the power company the right to eminent domain, which is considered to be in doubt

Commercial Intelligence.

THE WEEK IN TRADE.—The better weather has improved distributive trade in some sections, but the situation as a whole is more irregular, and trade is behind that of a year ago. Cereal crops, especially winter wheat, show improvement, but cotton reflects droughty conditions in the South Atlantic and Gulf states, while good reports come from west of the Mississippi. The industrial situation is not so satisfactory, a slowing down being noted in many industries. Current railway earnings are still on the decline from a year ago; clearings are running smaller, and prices tend downward. In the iron trade, finished products are rather quieter. Orders for 1,000 cars are reported placed at Chicago. At Pittsburg the iron trade is lifeless and milling operations are irregular. There is a congestion of soft coal at lake shipping points owing to the suspension of the up-lake transportation. Some concerns are buying in the open market, finding it cheaper to do so than to operate their own mines. Anthracite is in good demand. The railroads are laying off large numbers of men, the services of at least 30,000, it is said, having been discontinued since the first of the year. The strike on the Lakes is tying up the ore and coal traffic, rendering idle many thousand of ore and coal miners, and others. The labor situation is generally unsettled. Among the metals copper was very dull and weak, and prices have again been reduced. Lake is quoted at 13c @ 13⅛c; electrolytic, 12¾c @ 13c, and casting stock 12½c @ 12¾c. The exports thus far this month have aggregated 11,186 tons. It is estimated that at the end of May the exportation will amount to about 13,000 tons, which, while being large in comparison with the figures of a year ago, will show a decrease as compared to the extraordinary shipments of the last few months. *Bradstreet's* reports the number of business failures for the week ending May 26th as 184, against 215 the previous week and 181 the corresponding week last year.

PROGRESS IN STEAM TURBINES.—It has already been announced that the immense power station of the Pennsylvania, New York and Long Island Railroad, and the Philadelphia Rapid Transit Subway system of Philadelphia are being equipped with steam turbines aggregating at the start 33,000 kw. capacity; but of more immediate interest is the fact that the Interborough Rapid Transit Company of New York and the Brooklyn Rapid Transit system have both adopted steam turbines of the Westinghouse-Parsons type for extensions in power. The equipment of these systems will be in units of 5,500 kw. each, thus conforming to the precedent established by the Pennsylvania and Philadelphia systems in regard to the capacity of their largest main generating units. The Philadelphia Rapid Transit Company have also recently extended their original order for 16,500 kw. in Westinghouse-Parsons turbines by 6,000 kw. in four units of 1,500 kw. each. In the electric light and power field, the activity in steam turbine introduction still increases. Two 1,000-kw. Westinghouse-Parsons turbines will form the additional equipment to the present power system of the West Virginia Pulp and Paper Company at Piedmont, W. V. The United Electric Light Company of Springfield, Mass., have contracted for a 1,000-kw. unit for their power station at Springfield. A contract has been recently closed with the Merchants' Light, Heat and Power Company of Indianapolis, Ind., for two 750-kw. turbine units for general light and power service. The Iowa and Illinois Traction Company of Clinton, Ia., will shortly install two 400-kw. turbine units for furnishing additional power to their present railway system. An installation of peculiar interest as being the first to be placed in service in American mining work will be that of the Newhouse Mines and Smelter Company, who will install two 400-kw. units at their Cactus Mines, near Frisco, Utah. Turbines will furnish electric power for lighting the buildings and mines, and for all kinds of power throughout the entire property.

EXTENSIVE MEXICAN POWER PROJECTS.—Jose Maria Volasquez and Miguel S. Macedo, of Mexico City, the first named being a prominent engineer, have been accorded permission by the Mexican Government to establish an extensive electric power and irrigation system in the Iguala district, State of Guerrero. The waters of the Tuxpam, Lagoǒn, Amates and Tubpam rivers will be utilized. They have also applied for the necessary concession from the Mexican authorities in order to use 20,000 liters of water per second from the Tomatal River, State of Guerrero to operate an hydraulic plant for lighting purposes principally.

EXPORTS OF MANUFACTURERS in the fiscal year which ends with this month seem likely to exceed those of any preceding year. Ten months' figures just presented by the Department of Commerce and Labor through its Bureau of Statistics exceed those for the corresponding period of any preceding year. The fiscal year 1900 was the banner year in exports of manufactures, but the figures of ten months' exports of manufactures in the fiscal year 1904 exceed by nineteen million dollars those for the corresponding months of the fiscal year 1900. The total value of manufactures exported in the ten months ending with April, 1904, was $371,712,301, against $352,671,206 in the same period of the fiscal year 1900, which, as already indicated, made the highest record of manufactures exported prior to the fiscal year 1904. The fact that the present fiscal year has only two months' record to make and is nineteen millions ahead of the highest figure for the corresponding period in any preceding year (1900) seems to justify the prediction that the exports of manufactures in 1904 will be greater than those of any earlier year. The total value of manufactures exported in the full fiscal year 1900 was $433,851,756. Should the present excess of 1904 over 1900 continue during the remaining two months of the year it would bring the grand total of exports of manufactures up to $450,000,000. The export of manufactured products in ten months in 1894 was $153,466,065 or less than half what it is now.

THE STERLING COMPANY is building switchboards and additional switchboard equipment for Newark, Ohio; Francesville, Ind.; Janesville, Wis.; Waverly, Ohio; Flat Rock, Ill.; Broadhead, Wis.; Austinburg, Ohio; Newton, Ill.; Carson City, Mich. It is also furnishing its various types of combined cross connecting rack and protectors at Newark, Ohio; Centerburg, Ohio; Gambier, Ohio; Wilkshire, Ohio; Baltimore, Md.; Sheboygan, Wis.; Danville, Ill.; Lebanon, Ind.; Cleveland, Ohio; Wayne, Neb.; Coschocton, Ohio; Donora, Pa.; Louisville, Ky.; Ardmore, I. T.; Portland, Me.; Dexter, Mich, and Wessington Springs, S. D. The company has secured the contract to furnish the Standard Oil Company, of Albany, N. Y., with one of its latest type of private branch switchboards, and it isnow manufacturing a 5,000-capacity, 1,200-line multiple switchboard for the Home Telephone Company, at Tiffin, Ohio. This board is to be its new type of lamp signal magneto switchboard and will be among the first lamp signal multiple switchboards installed in the United States. The Sterling Company is, besides the above, furnishing additions and switchboard equipment for the following cities: St. John, Wash.; Wessington Springs, S. D.; Hamilton, Mo.; Chardon, Ohio; Roanoke, Va.; Johnson City, Ill.; Indianapolis, Ind.; Lorain, Ohio; Des Moines, Ia.; Hoopeston, Ill. They are also furnishing its different types of protector apparatus for the following cities: Warren, Pa.; St. Louis, Mo.; Spirit Lake, Ia.; Alexandria, Ohio; Butler, Pa.; Tampa, Fla.; Johnstown, Pa.; Chardon, Ohio; Pittsburg, Pa.; Sedalia, Mo.; Flushing, Ohio; Buckley, Ill.; Kansas City, Mo.; Superior, Wis.; New Bremen, Ohio; Utica, N. Y.

SOME C. & C. ORDERS.—The C. & C. Electric Company, 143 Liberty street, has secured a Canadian contract for nine motors varying in capacity from 5 hp. to 10 hp. to drive Hoe presses by means of Renold chains in a large Toronto lithographic plant. Various domestic orders have been received recently from Maryland, New Jersey, Pennsylvania and New York. The demand has been particularly good for small motors. The Baltimore *Sun* plant is to have two 35-hp. series parallel equipments for driving Hoe quadruple presses. The International Phosphate Company, of Cartaret, N. J., has ordered another 50-kw. belted generator. The Mauch Chunk (Pa.) Heat, Power and Electric Light Company has ordered twelve motors varying in size from 1 hp. to 10 hp. for its customers. A 50-kw. direct-connected generator has been ordered for the Brown Building, Wall Street. This is a repeat order. The engine will be Ball & Wood.

TURBINE PLANT FOR UNION METALLIC CARTRIDGE CO.—Westinghouse-Parsons steam turbines are to be installed in the new power station of the Union Metallic Cartridge Company at Bridgeport, Conn. The initial installation will consist of two turbogenerating units, each of 500 kw. capacity, to operate in parallel, and furnish 440-volt, 3-phase current at 60 cycles for general power and lighting purposes in the various shops located within three or four blocks of the power station. The turbines will operate under 150 pounds steam, 28 feet vacuum, and possibly superheat. The installation is in charge of Mr. Samuel M. Green, consulting engineer, Holyoke, Mass.

EQUIPMENT FOR MEXICAN COTTON MILLS.—The purchase is pending of a 750-hp. equipment for the water power plant of the Santa Gertrudes Cotton Mills, State of Orizaba, Mexico, owned by Sir Weetman D. Pearson. Mr. A. E. Worswick, formerly chief engineer of the Federal District Railway Company of Mexico City operating the Wernher Beit line, is now consulting electrical expert for the Pearson people, who have considerable electrical work in prospect in the Southern republic, notably in regard to the conversion of the Vera Cruz tramways, of which Sir Weetman is president. Mr. Worswick has his headquarters for the present in Mexico City.

WAGNER-BULLOCK APPARATUS.—The Washington and Oregon Water Power Company has closed contracts with the Wagner-Bullock Electric Company for three 500-kw., 3-phase Bullock generators to furnish power to operate their electric road and lighting business in the country surrounding Walla Walla, Wash. The power station will probably be located at Milton. There will be sub-stations at that point and also at Pendleton and Walla Walla.

MEXICAN ELECTRIC RAILWAY PROJECT.—An electric railway is to be constructed between Puebla Nueva and Navidad del Puerto, in the State of Jalisco, Mexico, the first port north of Manzanillo on the Pacific slope. The line will be built by the owners of the Puebla Nueva mines, who are European capitalists. The material, equipment, etc., will be practically all purchased in the United States. The road will develop considerable contiguous territory.

VERA CRUZ POWER TRANSMISSION.—Mexican advices state that Antonio A. Moll is primarily interested in a scheme to utilize the waters of the River Ozolonpam, in the Canton of Acayucan, southern part of the State of Vera Cruz, for generating electric energy for transmission to various plantations operated by Americans in that part of the world. Mr. Moll proposes to make use of 10,000 liters of water per second.

GERMAN-AMERICAN CABLE.—We are advised by Felten & Guillcaume, of Mulheim on Rhine, that the new German-American cable on the cable steamer "Stephan" recently in port at New York, was made by the company now laying it, viz., the North German Cable Works (Norddeutsche Seecabelwerke Actiengesellschaft) of Nordenham, Germany, which is under the technical direction of the firm first named.

GREAT NORTHERN POWER PLANT.—The Great Northern Power Company, Duluth, Minn., are to instal vertical turbines and other apparatus to operate at 250 revolutions per minute under a head of 365 feet. It is proposed to have a 35,000 hp. plant in operation in 1905. The plans provide for an increase in capacity up to 80,000 hp. Another hydraulic installation of 12,000 hp. at a 70-foot dam is also proposed.

EQUIPMENT FOR NEW MAIDEN LANE BUILDING.—Percival Robert Moses, consulting engineer, 35 Nassau street, will draw up the plans and let the contracts for the equipment to be installed for light and power purposes in the twelve-story office building to be erected at 48-50 Maiden Lane, New York, by Mr. S. F. Myers, of that address.

LIGHTING OUTFIT FOR AUSTRALIA.—The engineering and contracting firm of Mackenzie, Quarrier & Ferguson, 114 Liberty street, has secured an export order for a 60-hp Harrisburg standard engine to be direct connected to a 35-kw. Western Electric generator. The equipment is to be shipped to Australia for lighting purposes.

POWER EQUIPMENT ORDERED FOR GUADALAJARA MINES.—Westinghouse generators and Pelton wheels are to be installed in a plant on the Thomas River, Territory of Tepic, Western Mexico. The power is to be used for operating the Central Mining Company's mines located in the Guadalajara district.

EQUIPMENT FOR BATTLESHIP INDIANA.—The U. S. battleship Indiana now being overhauled at the Brooklyn Navy Yard is to be equipped with three 100-kw. C. & C. generators direct connected to Forbes engines of 150-hp. capacity each. This equipment is to be used chiefly for lighting purposes.

MORE LIGHTING EQUIPMENT FOR VERA CRUZ.—The lighting system in Vera Cruz, Mexico, is to be increased. The contract is held on behalf of the original concessionaries' estate by Francisco Hernandez. An additional 500 kilowatt equipment will be installed in the power house.

DURANGO LIGHT AND POWER SCHEME.—Miguel Morga, of Yopia, State of Durango, Mexico, has applied to the Mexican Government for a concession which will permit of the utilization of the waters of the Sobrices River for operating a large electric light and power plant which he will build.

EQUIPMENT FOR MEXICAN SUGAR PLANT.—The Eastwick Engineering Company, Limited, of 42 Broadway, has secured a contract for the construction of a 1,000-ton sugar plant in Mexico, which will be installed with considerable electrical equipment for light and power purposes.

CHIHUAHAN LIGHT AND POWER PROJECT.—An extensive electric light and power plant is to be built at Guaynopita, State of Chihuahua, Mexico. The current will be generated by water power. Mr. J. W. Taylor, of El Paso, Texas, is primarily concerned in the enterprise.

CONDENSERS FOR TOKIO PLANT.—The Wheeler Condenser and Engineering Company, 42 Broadway, has secured a substantial contract for condensing equipment to be installed in the power station of the Tokio (Japan) Street Railway Company.

DIRECTORY OF ELECTRICAL ASSOCIATIONS, SOCIETIES, ETC.

(Published first issue of each month.)

AMERICAN ELECTROCHEMICAL SOCIETY. Secretary S. S. Stadtler, 39 S. 10th St., Philadelphia. Next meeting, St. Louis, Sept. 12-17, 1904.

AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION. Secretary, Dr. C. E. Skinner, New Haven, Conn. Next meeting, St. Louis, Sept. 13, 1904.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS. Secretary, Ralph W. Pope, 95 Liberty Street, New York. Meetings, last Friday each month.

AMERICAN RAILWAY, MECHANICAL & ELECTRICAL ASSOCIATION. Secretary, Walter Mower, 12 Woodward Avenue, Detroit, Mich.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS. Secretary, G. W. Tillson, Brooklyn, N. Y. Next meeting, St. Louis, Oct. 4, 1904.

AMERICAN STREET RAILWAY ASSOCIATION. Secretary, T. C. Pennington, 2020 State Street, Chicago. Next meeting St. Louis, Mo., Oct. 12 and 13, 1904.

ASSOCIATION OF EDISON ILLUMINATING COMPANIES. Secretary, W. S. Barstow, New York City and Portland, Ore.

ASSOCIATION OF RAILWAY TELEGRAPH SUPERINTENDENTS. Secretary, P. W. Drew, Milwaukee, Wis. Next meeting, Indianapolis, Ind., June 15 and 16, 1904.

CANADIAN ELECTRICAL ASSOCIATION. Secretary, C. H. Mortimer, Toronto, Ont. Next meeting, Hamilton, Ont., June 15, 16 and 17, 1904.

COLORADO ELECTRIC LIGHT, POWER & RAILWAY ASSOCIATION. Secretary, George B. Tripp, Colorado Springs, Col. Annual meeting last Wednesday in October.

CONNECTICUT STATE STREET RAILWAY ASSOCIATION. Secretary, E. W. Poole, Bridgeport, Conn. Annual meeting in November.

ENGINE BUILDERS' ASSOCIATION OF THE UNITED STATES. Secretary, D. Fleming, Harrisburg, Pa.

ELECTRICAL CONTRACTORS' ASSOCIATION OF NEW YORK STATE. Secretary, F. Fish, Rochester, N. Y. Next meeting, Utica, July 19, 1904.

ELECTRICAL TRADES SOCIETY (Member National Electrical Trades Association). Secretary, A. P. Eckert, 39 Cortlandt Street, New York. Board of Directors meets second Friday of each month.

ILLINOIS STATE ELECTRIC ASSOCIATION. Secretary, H. E. Chubbuck, LaSalle, Ill.

INDIANA INDEPENDENT MUTUAL TELEPHONE ASSOCIATION. Next meeting, Lafayette, June 28 and 29, 1904.

INDIANA PUBLIC UTILITIES ASSOCIATION. Secretary, A. M. Barron, South Bend, Ind. Next meeting, Indianapolis, Ind., Oct. 18, 1904.

INDEPENDENT TELEPHONE ASSOCIATION OF THE UNITED STATES OF AMERICA. Secretary, Frank G. Jones, 48 West Jackson Boulevard, Chicago. Next meeting, St. Louis, Sept., 1904.

INDEPENDENT TELEPHONE ASSOCIATION OF SOUTHERN INDIANA. Secretary, E. W. Pichardt, Huntingburg, Ind.

INTERNATIONAL ASSOCIATION OF MUNICIPAL ELECTRICIANS. Secretary, Frank P. Foster, Corning, N. Y. Next meeting, St. Louis, Sept. 13 and 14, 1904.

INTERNATIONAL ELECTRICAL CONGRESS. General secretary, Dr. A. E. Kennelly, Cambridge, Mass. Meeting, St. Louis, Sept. 12-17, 1904.

INTERSTATE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, E. M. Coleman, Louisville, Ky.

IOWA ELECTRICAL ASSOCIATION. Secretary, W. S. Porter, Eldora, Ia. Next meeting, Dubuque, Ia., April, 1905.

IOWA TELEPHONE ASSOCIATION. Secretary, C. C. Deering, Des Moines, Ia. Next meeting, second Tuesday, March, 1905.

KENTUCKY INDEPENDENT TELEPHONE ASSOCIATION. Secretary, James Maret, Mount Vernon, Ind.

MAINE STREET RAILWAY ASSOCIATION. Secretary, E. A. Newman, 471 Congress Street, Portland, Me.

MASSACHUSETTS STREET RAILWAY ASSOCIATION. Secretary, Charles S. Clark, 70 Kilby Street, Boston, Mass. Meets second Wednesday of each month, except July and August.

NATIONAL ARM, PIN & BRACKET ASSOCIATION. Secretary, J. B. Magers, Madison, Ind. Next meeting, St. Louis, July, 1904.

NATIONAL ELECTRICAL CONTRACTORS' ASSOCIATION OF THE UNITED STATES. Secretary, W. H. Morton, 44 Whitesboro Street, Utica, N. Y. Next meeting, St. Louis, Mo., September 14, 15 and 16, 1904.

NATIONAL ELECTRIC LIGHT ASSOCIATION. Secretary, Dudley Farrand, Newark, N. J.

NEW ENGLAND STREET RAILWAY CLUB. Secretary, J. H. Neal, 101 Milk Street, Boston, Mass. Meets last Thursday of each month.

NEW YORK ELECTRICAL SOCIETY. Secretary, G. H. Guy, 114 Liberty Street, New York.

NORTHWESTERN ELECTRICAL ASSOCIATION. Secretary, T. R. Mercein, 85 Michigan Street, Milwaukee, Wis. Next meeting, St. Louis, Sept., 1904.

OHIO STREET RAILWAY ASSOCIATION. Secretary, Chas. Currie, Akron, Ohio.

OHIO ELECTRIC LIGHT ASSOCIATION. Secretary, D. L. Gaskill, Greenville, Ohio. Next meeting, Sandusky, Ohio, Aug. 16, 17 and 18, 1904.

OHIO SOCIETY OF MECHANICAL, ELECTRICAL AND STEAM ENGINEERS. Secretary, C. J. Miller, Canton, Ohio.

PACIFIC COAST ELECTRIC TRANSMISSION ASSOCIATION. Secretary, G. P. Low, 600 Rialto Building, San Francisco, Cal. Next annual meeting June 21, 1904.

SOUTHWESTERN ELECTRICAL ASSOCIATION. Secretary, J. L. Ellis, Oklahoma City, Okla.

SOUTHWESTERN GAS, ELECTRIC & STREET RAILWAY ASSOCIATION. Secretary, Frank E. Scovill, Austin, Texas.

STREET RAILWAY ACCOUNTANTS' ASSOCIATION OF AMERICA. Secretary, W. B. Brockway, 40 Morris Street, Yonkers, N. Y.

STREET RAILWAY ASSOCIATION OF THE STATE OF NEW YORK. Secretary, W. W. Cole, Elmira, N. Y. Next meeting, Utica, N. Y., Oct. 11 and 12, 1904.

VERMONT ELECTRICAL ASSOCIATION. Secretary, C. C. Wells, Middlebury, Vt. Next meeting, Montpelier, Sept. 21 and 22, 1904.

WESTERN SOCIETY OF ENGINEERS, Electrical Section. Secretary, J. H. Warder, 1737 Monadnock Block, Chicago, Ill.

General News.

THE TELEPHONE.

MONTGOMERY, ALA.—The Eastern Shore Telephone Company has been incorporated at Fairhope.

BIRMINGHAM, ALA.—The Smith County Telephone Company has been incorporated with headquarters at Taylorville. The capital stock is $30,000.

RED BLUFF, CAL.—The Red Bluff & Paskenta Telephone Company has been incorporated, the capital stock being $5000. The incorporators are Albert, R. O. Snelling, E. D. Gardner and others.

SAN LUIS OBISPO, CAL.—The Sunset Telephone Company is rebuilding its entire system in this place involving an expenditure of about $20,000. A new multiple, central-energy switchboard will be installed in the exchange in place of the old-fashioned one now in use.

BOISE, IDA.—The Grangeville & Salmon River Telephone Company has been incorporated with a capital stock of $12,000. The directors are L. Hollingshead, J. O. Levander and others.

MANLIUS, ILL.—The Bureau County Mutual Telephone Company has increased its capital from $2500 to $20,000.

SAVANNAH, ILL.—The Carroll County Independent Telephone Company has increased its capital from $75,000 to $150,000.

ASSUMPTION, ILL.—The Assumption Telephone Company has been incorporated with a capital stock of $2400. The directors are S. S. Shafer, S. J. Long and others.

DELPHI, IND.—The Flora Bringhurst Telephone Company has been organized with W. G. Calene as president.

BLOOMFIELD, IND.—The New Home Telephone Company has authorized the issue of $100,000 preferred stock.

SEELEYVILLE, IND.—The Loss Creek Mutual Telephone Company has been incorporated with a capital stock of $3500. F. H. Felling, F. Conoway and M. Modesitt are directors.

EVANSVILLE, IND.—A resolution was introduced in the council at its last meeting that no action be taken on the telephone franchise question until the court's decision is handed down. This means that the Cumberland Company's claim must be removed before the franchise can be let to advantage—which means to the highest bidder.

COLUMBUS, IND.—The rivalry between the Hope and the Hartsville Telephone Companies is now at an end. Formerly each town had an exchange and the Hope line, owned by Frank Bowman, ran to Hartsville and the Hartsville line owned by A. J. Cottle, ran to Hope, Mr. Bowman has purchased the Hartsville line, and the two have been consolidated.

EVANSVILLE, IND.—The "Anti-Monopoly Telephone Company" has been organized in this city by manufacturers with a capital stock of $500,000. The company will ask for a 30-year franchise in a few days and will agree to pay the city a bonus of $125,000 in that time. The following well-known manufacturers were elected officers: B. F. Von Behren, president; R. Manheimer, vice-president; Henry Cook, secretary; E. Lyon, trasurer; A. L. Flickner, Joseph Kohlmeyer, E. Wile, W. S. Flickner and Fred Elmendorf, directors.

EVANSVILLE, IND.—In a meeting held here it developed that the way in which the Citizens' Telephone Company is to pay the debts of the old municipal scheme is through the purchase of the plans of the latter company. For a year employees were at work on plans for the plant to be installed by the municipal company. These are now held to be the chief assets and it is believed they can be sold for a sum sufficient to wipe out the indebtedness, and of course the only company that would need them would be the new concern coming into the field.

INDIANAPOLIS, IND.—The telephone capitalists from Pennsylvania and Ohio, headed by J. G. Splane, of Pittsburg, who have been inspecting the independent plants in the middle west and perfecting plans whereby an independent long-distance line from St. Louis to the Atlantic coast is to be constructed spent two days in Indianapolis inspecting the exchanges of the Indianapolis company and conferring with the officers of the New Long-Distance Telephone Company. Mr. Splane said that the arrangements had been completed and that the service would be given to the people as soon as a few short connecting lines can be constructed. He said no separate company will be capitalized for the long-distance line, but each of the large companies will construct and control the lines in its territory. The New Long-Distance Company will complete the lines in Indiana, the Kinloch in Illinois and Missouri, the United States in Ohio, the Independent Long-Distance Telephone & Telegraph Company of Louisville in Kentucky, and the Western Company in Kansas and Missouri. The plan of operation will be similar to the traffic arrangements between the railroads of the country.

WEBSTER CITY, IA.—The E. H. Martin Telephone Company has bought $10,000 worth of telephone cable from the Stromberg-Carlson Company.

KEOKUK, IA.—The Iowa Telephone Company will soon construct conduits for the wires in the downtown district. A site has been purchased for a new exchange building.

FRANKFORT, KY.—The Brandenburg & Big Bend Telephone Company, of Meade County, has filed articles of incorporation with a capital stock of $1050. The principal stockholders are S. B. Crecelius, William Green and M. J. Bennett.

EASTON, MD.—The Cecil Farmers' Telephone Company has been granted a charter to operate a system in Cecil County.

BANCROFT, MINN.—A new telephone company has been organized here with A. H. Henry as president.

ST. PETER, MINN.—Farmers of Lake Prairie and Lavasse have formed a company to build 18 miles of rural telephone line.

BILLINGS, MO.—The Billings Telephone Company has been incorporated with a capital stock of $10,000. The directors are J. Schmill, C. A. Dewitt and others.

ST. LOUIS, MO.—Financial arrangements have been completed by the Kinloch Long Distance Telephone Company of Missouri with a St. Louis banking syndicate whereby it, together with other leading independent companies of the country, will be enabled to perfect a trans-continental long-distance system. The Kinloch Company will shortly file a first mortgage deed of trust to the Mississippi Valley Trust Company, of St. Louis, trustee, covering all of the suburban and interurban properties embraced in the long distance service, to provide additional capital for extra outlays needed for additions, extensions and other like improvements. Rate agreements have been formed between all of the various independent telephone companies, situated between Pittsburg and Kansas City, whereby the service will be in operation within the next few months.

BILLINGS, MONT.—The Billings Mutual Telephone Company and the Montana Telephone Company, which will operate here and in eastern Montana, have filed articles of incorporation. The former has a capitalization of $40,000 and the latter $10,000.

WAYNE, NEB.—The Wayne Independent Telephone Company has filed articles of incorporation, the capitalization being $15,000. The officers are: President, Thomas H. Fritz, vice-president, Irving E. Huff; secretary, Frank E. Bell, and treasurer, Andrew N. Matheny.

CONCORD, N. H.—The Independent Telephone Company will install a system in Claremont, Newport and Sunapee.

ROCHESTER, N. Y.—The Hamlin Rural Telephone Company has filed articles of incorporation with a capital stock of $5000.

COOPERSTOWN, N. Y.—The Otsego Home Telephone Company has been incorporated with a capital stock of $40,000. F. C. and A. A. Ward are the directors.

GLENS FALLS, N. Y.—The stockholders of the new Union Telephone Company of this place have voted to consolidate with the Troy and Saratoga independent companies.

POTSDAM, N. Y.—The Northern Union Telephone & Telegraph Company has been incorporated with a capital stock of $50,000. The directors are A. B. Thompson and others.

ALBANY, N. Y.—The South Bethlehem Telephone Company has been incorporated with a capital stock of $2000 to establish a telephone line between South Bethlehem, Selkirk and Cedar Hill. The directors are E. C. Palmer, Charles D. Niver, J. R. Davidson, of South Bethlehem; Newton B. Vanderzee, John W. Mosher, John B. Mosher and John F. Vrooman, of Selkirk.

STRYKER, OHIO.—The Stryker Telephone Company has increased its capital from $10,000 to $15,000.

CLEVELAND, OHIO.—The Citizens' Telephone Company, of Cleveland, has increased its capital stock from $40,000 to $50,000. Mr. H. W. Bolles is president.

OTTAWA, OHIO.—The Ottawa Mutual Telephone Company has been incorporated with a capital stock of $1000 by C. O. Beardsley, J. H. Purnell, F. E. Smith, E. L. Tapper and George Fritz.

SUMMERFIELD, OHIO.—The Summerfield Telephone Company has been incorporated with a capital stock of $5000. The directors of the company are J. H. Sparling, William Simmons and others.

GILBERT, OHIO.—The Gilbert Telephone Company, with a capital stock of $2000, has been incorporated by E. L. Roe, Chalmer Menafee, H. L. Nye, J. B. Rhodes, W. M. Bateman and S. W. Wipn.

COLUMBUS, OHIO.—The Alvordton Telephone Company has been incorporated with a capital stock of $10,000. The incorporators are A. L. Bigelow, D. C. Lord, C. F. Poulson, P. C. Bigelow and V. E. Cunningham.

COLUMBUS, OHIO.—The Citizens' Telephone Company is extending its service and expects to install 4000 new telephones during the summer. The company expects to have its automatic switchboard installed the first of next year.

CINCINNATI, OHIO.—It is reported that a combination may be effected of all the independent telephone companies seeking to establish systems in Cincinnati, except the Queen City Telephone Company, whose application is now being heard in the Probate Court. The proposed combination will include the Interstate Telephone Company, the Fitzsimmons Telephone Company and the Cincinnati Telephone Company.

ORWELL, PA.—The People's Co-operative Telephone Company, of Orwell, has recently been organized with the following-named officers: President, E. D. Chaffee; vice-president, J. C. Petts; secretary, H. G. Newell; treasurer, E. B. Arnold.

COOKEVILLE, TENN.—The Gainesboro Telephone Company has petitioned for a franchise to establish an electric light plant in Cookeville.

GREEN BAY, VA.—The South Side Telephone Company has completed its line between this place and Farmville.

SPOKANE, WASH.—The Interstate Telephone Company contemplates building a line from this city to Harrison, Idaho, a distance of 200 miles.

OSHKOSH, WIS.—The Kirchhayne & Cedarburg Telephone Company, of Washington County, has increased its capital stock from $500 to $1500. Mr. William Tischerson is president, and W. P. Jocham, secretary.

PETERBORO, ONT.—The council for the city of Peterboro has granted to the Canadian Machine Telephone Company a ten years' franchise. The price for telephones must not exceed $15 per year for residences, and $20 per year for business. The wires and cables must be placed underground on the principal streets.

WALKERVILLE, ONT.—The town council of Walkerville has refused to renew the franchise of the Bell Telephone Company unless the company pays more money for its privilege. The town of Sandwich, Ont., some time ago also refused to renew its franchise to the company on precisely the same grounds.

Electric Light and Power.

LEWISVILLE, ARK.—The Lewisville Light & Water Company, of Lewisville, has been incorporated. Capital, $25,000. E. B. Daniel is president, and G. W. Dobson, secretary.

LOS ANGELES, CAL.—John Johnson, Jr., representing Los Angeles parties, has asked for franchises for gas and electric plants at Oceanside and Escondido.

FRESNO, CAL.—The San Joaquin Power Company is figuring on two more water power plants in the mountains and additional steam capacity in Fresno of about 1500 kw. The company will also build an additional pole line to the power houses from Fresno, a distance of 36 or 40 miles.

SANTA CRUZ, CAL.—Articles of incorporation of the Watsonville Light & Power Company have been filed with the County Clerk. The stockholders are Fish M. Ray, Oakland; Joseph C. Love, Berkeley; David H. Foote, San Francisco; Charles W. Waller, San Francisco; A. W. Linforth, San Francisco.

LOS ANGELES, CAL.—The Los Angeles Gas & Electric Company will vote on June 15 on a proposition to create a bonded indebtedness of $4,000,000, to be secured by a deed of trust on all the properties of the corporation, which is the result of the recent consolidation of the Los Angeles Lighting Company and the Los Angeles Electric Company.

HARTFORD, CONN.—The Hartford Electric Light Company has secured the contract for lighting the city at $70 for each lamp per year for a period of 5 years.

KISSIMMEE, FLA.—The Kissimmee electric light plant will install a 120-hp engine and a dynamo of 1500 lights capacity.

TIFTON, GA.—The Tifton Ice & Power Company contemplates installing a large engine and dynamo in its plant at this place.

BLUE RIDGE, GA.—The Blue Ridge Electric Light & Power Company will enlarge its plant during the summer. Water power will be used for the operation of the plant.

WASHINGTON, GA.—It is expected that a 100-kw alternating current two-phase generator will be installed in the municipal electric light plant in this place. An electric pump will also be installed at the water works.

GRIFFIN, GA.—This town will issue $40,000 bonds in two or three months for the improvement of the electric light and power plant. Full information can be obtained by addressing J. M. Browner, Chairman of the Light, Water and Sewerage Commission.

GOLCONDA, ILL.—A franchise has been granted for an electric light plant, to cost $4000. J. O. Williamson is manager.

MT. VERNON, IND.—It is reported that the Mt. Vernon Electric Light Company will soon ask for bids for the construction of a plant.

ELKHART, IND.—The St. Joseph & Elkhart Power Company is said to be considering the extension of its system to Goshen, Laporte, Wakarusa and Syracuse.

MT. VERNON, IND.—The Mount Vernon Electric Light & Power Company has filed articles of incorporation with the Secretary of State. The capital stock is $15,000. R. D. Morris, G. V. Menzies and others are the incorporators.

WABASH, IND.—The Wabash Water & Light Company has incorporated with a capital stock of $160,000. Thos. W. McNamee, of Wabash, W. G. Snow, Montclair, N. J., and Edmond Le B. Gardner, of Ridgewood, N. J., are directors.

BOONEVILLE, IND.—The City Light & Power Company has been awarded the contract to light the city. The company's new plant will be pushed to completion. The contract accepted is liberal, in that it gives the city complete control, thus avoiding any possibility of excessive prices in the future. The city reserves the right to lease or purchase the plant at its option.

INDIANAPOLIS, IND.—The Merchants' Heat & Light Company will improve and enlarge its plant, increasing its capacity at least 150 per cent. The improvements will cost $250,000 or $300,000. The present powerhouse will be doubled in size and the new equipment will include 2500-hp, additional boiler capacity and two new Westinghouse turbine engines of 1150-hp each. The boilers will be equipped with the automatic chain grates.

WILTON, IA.—Bonds of $5250 have been voted to improve the electric light plant at this place.

DANVILLE, KY.—The City Council has decided to offer for sale a franchise to light this town by electricity.

CALDWELL, KY.—The Caldwell Electric Light & Power Company has been incorporated with a capital of $15,000.

STURGIS, KY.—J. M. Cartwright, Town Clerk, writes that the town would like some one to take a franchise and construct and operate an electric light plant here. The population is 1400.

BRANDON, MAN.—The Western Electric Light & Power Company, of Brandon, has been granted a charter. The company is to install an electric plant on the Assiniboine River, about 9 miles below Brandon. The capital of the company is fixed at $300,000, the provisional directors being J. M. Robinson, William Currie, William Alexander, B. Smith and John Russell, of Brandon. The company in the near future will establish a telephone system as well.

BALTIMORE, MD.—The Board of Awards has approved the specifications of the Electrical Commission for 1,000,000 feet of duct material and 250,000 feet of special duct pipe.

BALTIMORE, MD.—The Maryland Telephone & Telegraph Company has a force of men at work drawing cables through the conduits for the purpose of supplying electric light and power, the ordinance giving it this privilege having been passed and signed by the Mayor. At present the company will supply current from the Purnell plant, which it has purchased. The company intends to build a new central station at a cost of $1,500,000, and it is stated that it has options on waterfront property for this purpose.

MATTAPAN, BOSTON, MASS.—The Mattapan Gas & Electric Light Company, of Boston, has been incorporated, with a capital of $10,000. John H. Doherty is president.

EXCELSIOR, MINN.—Dr. F. B. Kramer has petitioned for a franchise for an electric light plant and water works.

BAY ST. LOUIS, MISS.—Mr. A. L. Stoker, owner of the electric light plant here, intends to put in a new engine and direct connected generator.

BATESVILLE, MISS.—The Panola Electric Light & Power Company contemplates building a line to Sardis at an early date, and lighting this town from the Sardis plant. The distance between the two places is nine miles.

SEDALIA, MO.—A charter has been granted the United Water, Gas and Electric Company, of Sedalia, with a capital of $1,000,000. The company has consolidated the Sedalia water, gas and electric companies.

ADDISON, N. Y.—The electric light plant owned by F. H. Wheaton was destroyed by fire May 13.

GRANVILLE, N. Y.—The Granville Gas & Electric Light Company is surveying for the construction of its dam at Lake St. Catherine.

HUNTER, N. Y.—The Tannersville Electric Light & Power Company has been organized with a capital of $20,000. Incorporators: Jacob Fromer, Geo. Haner, and Cyrus Showers, all of Tannersville.

KINGSTON, N. Y.—A corps of surveyors headed by Mr. Denman, of Ellenville, is engaged in locating the line for the poles and wires to bring electrical power from the Honk Falls power plant to this city for the Honk Falls Power Company.

ORRVILLE, OHIO.—The Orrville Light, Heat & Power Company will extend its street lighting system.

NEW CASTLE, PA.—The finance committee has recommended the issue of $85,000 bonds for a municipal electric light plant.

ELWOOD CITY, PA.—The Elwood Power Company contemplates establishing sub-stations at West Pittsburg and Zelenopile, and will complete 24 miles of high tension pole line.

MEMPHIS, TENN.—The North Arkansas Electric Railroad & Power Company, of Mount Hersey, Newton County, has filed articles of incorporation. Capital stock, $150,000, of which $30,000 has been subscribed. The officers are Griff Glover, Bloomfield, Mo., president; E. K. Eby, Jasper, Ark., vice-president; S. J. Norman, Jasper, secretary and treasurer.

DE LEON, TEX.—C. L. Rocker will install an electric light and power plant at De Leon.

NEW BRAUNFELS, TEX.—The Landa Electric Light & Power Company contemplates rebuilding one of its lines and otherwise improving its system at an early date. Mr. Louis A. Voigt is electrician.

BROWNSVILLE, TEX.—The city council of Brownsville has revoked the franchise which it granted several months ago to J. W. Macy, of Houston, for the establishment of an electric light plant and water works system here, and has granted a similar franchise to Judge James B. Wells, of Brownsville. Judge Wells says that he will soon commence the installation of the electric light and power plant and that he will also install a similar plant in Matamoros, Mexico, situated opposite Brownsville.

OGDEN, UTAH.—A recent electrical storm here caused damage to transformers and other machinery of the Utah Light & Railway Company to the extent of $15,000.

SALT LAKE CITY, UTAH.—The Gold Development Company has filed on the waters of Bullion canyon, as the first step towards the establishment of a power plant at that point.

OGDEN, UTAH.—It is reported that the Utah Light & Railway Company will establish a sub-station near the center of city for the betterment of electric lighting and power supply service.

SALT LAKE CITY, UTAH.—The Pan Power & Electric Company, of Utah, has been organized in Salt Lake City, with a capital of $10,000. Wm. D. Cameron is president; Jas. A. Mahon, secretary.

SALT LAKE CITY, UTAH.—The city council has under consideration a proposition submitted by Garff & Son, of Logan, Utah, to establish a large power plant here for the lighting of the city, with the understanding that in ten years the entire plant is to be deeded over to the city. The company estimated that $200,000 will cover the cost of the plant.

DANVILLE, VA.—A new electric light plant established by the municipality is now in operation and this place is now for the first time lighted by electricity. The plant is so arranged that it is possible to use either water or steam power alone or both together. The maximum capacity of the water power plant is 170-hp and this is reinforced by the steam plant, according to the requirements.

LADYSMITH, WIS.—The Ladysmith Light & Power Company contemplates the installation of series arc lights and the development of a water power.

MARSHFIELD, WIS.—R. L. Kraus is interested in forming a stock company to develop electric power at the dam of the Consolidated Water Power & Paper Company.

ST. MARYS, ONT. The St. Marys Corporation expects to install new machinery next fall.

OTTAWA, ONT.—The city of Ottawa, some two years ago, voted for a civic lighting system, but at a recent meeting of the city council, in spite of the voice of the citizens, the Ottawa Electric Company was given a contract for street lighting for a period of ten years at $52 per light. Although this is a very favorable contract and a reduction of some $13 per lamp, yet there is much indignation manifested by the ratepayers that their wishes have been disregarded. The report of experts showed that the city could do its own lighting for $38 per lamp per year. Ottawa, therefore, stands to lose $80,000 over the ten years which the contract is to run.

THE ELECTRIC RAILWAY.

OPELIKA, ALA.—The organization of the Opelika Railway, Light & Power Company was effected a few days since by the election of the following officers: J. B. Green, president; Rush Taylor, first vice-president; Bartow Smith, second vice-president; W. C. Robinson, secretary and treasurer. The plan is to build an electric railway from Opelika to Auburn and furnish light and power for both places. The capital stock is to be $300,000.

ALTON, ILL.—The merger of the Alton Light & Traction Company and the Granite City Electric Street Railway Company has been effected. This will unite several hundred miles of street railway and will connect Alton to St. Louis and intermediate points. Work will be commenced at once toward connecting the two systems of street railways. A called meeting of the directors of the two companies has been asked for on June 14, at which propositions will be considered for increasing the capital stock of the two companies from $1,000,000 each to $3,000,000 jointly.

CHICAGO, ILL.—What promises to be one of the most important enterprises yet undertaken in the way of electric railway building in Indiana was put under way the other day, when the Chicago and Northern Indiana Railroad Company filed articles of incorporation. This company purposes to build an electric railway from Chicago to Indianapolis, through Lake, Porter, Jasper, Pulaski, White, Cass, Howard, Clinton, Tipton, Hamilton and Marion counties into Indianapolis over a private right of way. The directors of the company are Lester Soule, A. L. Wheeler and Senator Charles N. Thompson, of this city; Henderson E. Davenport, Sheridan; James G. Kemp, Kempton; Martin W. Eikenbury, Russiaville, and Luther McDowell, Young America. The nominal capital stock is $25,000, of which Mr. Soule holds $15,000. It is said, however, that millions are back of the project, and that it has the support of several wealthy men of the State who are not among the incorporators. Mr. Soule is president and general manager of the Globe Construction Company, of Des Moines, Iowa, which holds the contract for building the Indianapolis and Logansport steam road. An official of the company says that the road will operate in competition with all steam roads covering the territory; that freight and passenger traffic will be carried on just the same as on steam roads, and that the line will be equipped with standard passenger cars and Pullman sleepers.

PRINCETON, IND.—The Evansville & Princeton Traction Company has completed a survey of an extension from Princeton to Vincennes. White River will have to be crossed near Hazleton. When this line is built only one gap will remain to be closed up to afford through service between Evansville and Indianapolis. This gap is one of 30 miles between Brazil and Danville.

LAWRENCEBURG, IND.—The Cincinnati, Lawrenceburg & Aurora Electric Street Railway Company has increased its capital stock from $750,000 to $1,000,000, in order to obtain funds to complete the betterments, extensions and changes of route necessary for the successful operation of the business of the company, and for the purpose of increasing its working capital. J. C. Hoover is president and Stanley Shaffer, secretary.

TERRE HAUTE, IND.—The Terre Haute Electric Traction Company has changed its name to Terre Haute Traction & Light Company. The company has also filed amended articles of incorporation thereby enlarging the purposes for which the corporation was formed, and naming additional cities and towns in which, and in the vicinities of which, it is proposed to carry on operations. In short, the company will extend its lines through Clay, Vermillion, Clinton and Greene Counties.

MUSKOGEE, I. T.—The City Council has granted a street car franchise to Capt. Ira L. Reeves and N. A. Gibson.

LEXINGTON, KY.—The Blue Grass Traction Company, operating from Lexington to Paris, Ky., and from Lexington to Georgetown, Ky., has sold $700,000 of 5 per cent. bonds, a considerable portion of which were taken in Cleveland and the balance in Cincinnati and Lexington, Ky. The Cleveland Trust Company is trustee for the mortgage.

BILOXI, MISS.—Capt. W. K. Penny has been granted a charter for the construction of an electric railway between Biloxi and Pass Christian.

PHILADELPHIA, PA.—The directors of the Public Service Corporation have declared the semi-annual dividend on the stock of the South Jersey Gas, Electric & Traction Company and confirmed the lease of the Camden & Suburban Company.

POTTSTOWN, PA.—Application for a charter has been made by the Pottstown & West Chester Improvement Company, which has been formed with a capital stock of $400,000. This is the company of which C. Wesley Talbot, ex-Burgess of West Chester, is president. The plant is to build an electric railway between Pottstown and West Chester.

JOHNSTOWN, PA.—It is reported that the Johnstown Coal & Coke Company, owning mines at Moss Creek, has become interested in the plan to build an electric railway from Johnstown to Spangler and Moss Creek. The mines of the company are at present very inaccessible, and it is said that the company, in connection with local people, will go into the project and finance the deal.

NEW CASTLE, PA.—A complete reorganization has been effected of the Pennsylvania & Mahoning Valley Electric Railway Company, which controls the local and Youngstown systems and about 100 miles of tracks throughout Eastern Ohio. Superintendent M. E. McCaskey is made second vice-president and general manager of the entire system. W. C. Smith, of Youngstown, is now general manager under Vice-President McCaskey. The local offices are made the general offices, and the Youngstown clerical force will be brought here.

WELLSBURG, W. VA.—H. G. Lazear, of Wellsburg, promoter of the proposed electric railway between Wellsburg and Bethany, is now in New York negotiating with the Westinghouse Company for the construction of the line.

NEW INDUSTRIAL COMPANIES.

THE ARNOLD ELECTRIC MANUFACTURING COMPANY has been incorporated with a capital stock of $3000, by G. L. Clegg, C. H. Crawford and Leon Stroh.

THE GENEVA ELECTRIC COMPANY has been incorporated in Geneva, Ohio, with a capital stock of $5000, by Homer Hood, Marcus Westerman, Lewis H. Young, Abner G. Webb and Harry B. Gregory.

THE CATARACT ELECTRIC SUPPLY COMPANY, with a capital stock of $100,000, has been incorporated at Buffalo, N. Y., the directors being N. S. Hallett, F. T. McDonald and E. B. Collister, Buffalo.

THE PRESSED STEEL POLE COMPANY, of Jersey City, has been incorporated with a capital stock of $125,000. The names of the incorporators are C. L. Wilson, John Roland, N. B. Neaghy and E. A. Kelly.

THE AMERICAN GARAGE & MAINTENANCE COMPANY, of New York, has been incorporated with a capital stock of $100,000. The incorporators are J. T. Rainier, P. N. Lineberger and H. U. Kibbe, New York.

THE COMMONWEALTH ELECTRIC COMPANY, of Jersey City, has been incorporated in New Jersey with a capital stock of $100,000. The incorporators are Graham Sumner, Ross A. Mackay and Mark Hyman.

THE F. C. THOMPSON COMPANY has been incorporated in New York for the purpose of manufacturing scientific instruments. The capital stock is $25,000 and the incorporators are F. C. Thompson, F. M. Ashley and Hattie A. Dean, New York.

THE CONSTANT DYNAMO COMPANY has been incorporated at Portland, Me., to manufacture electrical apparatus. The capital stock is $5,000,000, of which $250 is paid in. The officers are: President, Harry L. Cram, of Portland; treasurer, Charles Howard Weston, of Boston.

THE ELECTRIC CONSTRUCTION COMPANY has incorporated at Elkhart, Ind., with a capital stock of $25,000. The company will establish its principal office and plant in Elkhart for the purpose of manufacturing electric batteries and electrical appliances and other mechanical devices. Ernesto Sassenhoff, L. B. Hornbeek and B. R. Reid are the incorporators.

LEGAL.

CLEVELAND FIVE-CENT FARES.—Justice White, of the United States Supreme Court, has handed down a decision affirming the decision of the United States Circuit Court for Northern District of Ohio in the Cleveland (Ohio) Street Railway fare cases. The opinion was favorable to the railway. The cases involved the validity of the ordinance passed by the City Council of Cleveland in 1898, fixing the rate of fare on the street railways at 4 cents cash, or seven tickets for 25 cents. The Supreme Court held that the consolidation ordinance of 1885, fixing fares at 5 cents, constituted a contract binding both on the city and the railway companies.

TELEPHONES IN POOL ROOMS.—Some of the lawyers for the poolroom men have made demands upon the New York & New Jersey Telephone Comapny to replace the telephones which were ripped out of poolrooms by the police recently. The telephone company stated that the matter would be referred to the law department of the company and the contracts examined. Many of the poolroom men had made contracts with the company for a year, and declare that the company must replace the instruments which the police seized or stand suit for damages. It is the intention of the poolroom men to bring such suits, not in the guise of poolroom owners, but as regular subscribers whose contracts have been broken.

CHICAGO TROLLEY FRANCHISES.—A decision, which in effect upohlds the so-called ninety-nine-year act, but restricts application, was announced in Chicago last month by Judges Grosscup and Jenkins in the United States Circuit Court. The decision says the act applies to all ordinances and grants made by the City of Chicago up to the adoption of the city charter in 1875, but does not apply to grants after that date. Mayor Harrison said the city would appeal so as to get a final decision from the United States Supreme Court. The "Ninety-nine-Year Act" is a statute passed by the Illinois Legislature many years ago granting the street car companies in Chicago practically a free hand if the contentions of the companies were accepted. The validity of the act and the scope claimed have been bitterly contested by the city, one of the grounds of attack being the allegation that the enactment was obtained dishonestly.

SECOND-HAND LAMPS ENJOINED.—In the United States Circuit Court for the District of New Jersey the following injunction was granted on May 16th, 1904, by Judge Archbald, in the case of the General Electric Company vs. McKeon et al. "This motion having come on to be heard on the sixteenth day of May, 1904, upon the pleadings and affidavits of both parties filed herein, and having been argued by Charles Neave, Esq., on behalf of the complainant and by William J. Kearns, Esq., on behalf of the defendants, and due consideration having been had, it is ordered that a preliminary injunction issue out of and under the seal of this court directed to the defendants, William F. McKeon and Joseph Conning, strictly enjoining and restraining them and each of them and their servants, employees, agents and workmen from directly or indirectly selling or otherwise disposing of any old or second-hand "Edison" incandescent electric lamps without plainly and unmistakably marking them and each of them with the words "Used and Second-hand," until the further order of this court." It appears that two other preliminary injunctions of similar character have been issued against other persons.

NEGLECT OF ELECTRIC LIGHTING COMPANY.—The Supreme Court of Pennsylvania has recently handed down a decision in the suit of Daltry vs. Media Electric Light, Heat & Power Company, holding as follows: 1. An electric light company is bound to use the highest degree of care practicable to avoid injury to any one liable to come accidentally or otherwise in contact with its wires. 2. Where an electric light company negligently permits its wires to come in contact with the wire of another, thereby causing an accident, it is responsible for the injury resulting. 3. Where an owner of a house procured defendant electric light company, at his own expense, to introduce electric light into the house by running a wire from its line at the gateway across the lawn to the building, and on the removal of such person from the house the company cut off electric connection, but left the wire hanging in connection with the feeder line to the street, it was not relieved from liability to a boy injured by coming in contact with such wire by the fact that it was not the owner. 4. Where an electric light company left a wire connected with its plant hanging from a pole in the lawn of another to within a few inches of the ground, and a boy was injured by coming in contact therewith, it was no defense that the boy was a trespasser on the land at the time of the accident. 5. Evidence in an action against an electric light company to recover for injuries received by coming in contact with a wire of the company is held to sustain verdict for plaintiff.

OBITUARY.

DR. ADOLPHO ASCHOFF, of the Brazilian electrical engineering and contracting firm of Aschoff & Guinle, of Rio de Janeiro, which concern represented the interests in that part of the world of a score of leading American electrical manufacturing firms, including the General Electric Company, is dead. When last in this country, where he had many warm friends and admirers, Dr. Aschoff was in very poor health. His first visit to the United States was made in 1893 when he was attached to the Brazilian Commission at the Chicago Exposition. He leaves a wife and one daughter.

WILLIAM WALLACE.—Mr. William Wallace, who was one of the founders of the firm of Wallace & Sons, at Ansonia, Conn., died at his home in Washington, May 20, in the eightieth year of his age. Mr. Wallace was a native of England, where he was born in 1825. He was at one time associated with Professor Moses G. Farmer, and in 1876, at the Centennial Exposition, he brought out the Farmer-Wallace dynamo machine with which the buildings were successfully lighted, this being one of the earliest applications of electric lighting in this country. He made several improvements in arc lighting apparatus. Mr. Wallace was greatly interested in scientific matters and had a laboratory fitted up in his house for experimental work. For some years he lived quietly in Washington. He is survived by a son, who lives in Rochester, N. Y., and a daughter who has been his companion for several years. In February, 1893, Mr. W. J. Hammer contributed to the columns of THE ELECTRICAL ENGINEER, of which this journal is the successor, a brilliant series of articles on Mr. Wallace's work, profusely illustrated with original photographs and other material. In these articles the interesting fact is mentioned that Mr. Wallace was an Englishman, having been born in Manchester, March 16, 1825, and coming to America with his parents in 1832. His people were among the early settlers of Ansonia, Conn., where they developed pioneer branches of the copper and brass industry. It was out of such work that grew the connection of Mr. Wallace with electrical affairs and his close intimacy with such men as Farmer, Edison, Sprague, Prof. Barker and many other celebrities. The first Wallace dynamo machine dated back to 1874, and at the Centennial Exposition as well as at later exhibitions several interesting pioneer types of such machinery produced at the Wallace works were shown. In 1875 Mr. Wallace began making arc dynamos and some of his arc lamps, among the earliest known in the country, were used at the Centennial. In fact, Mr. Wallace invented and constructed the first arc lamp made in this country, with plate carbons adjustable by hand. Mr. Wallace also was the first here to run arc lamps in series, and one of the first four operated in this manner is now among the relics in the possession of Columbia University, New York City. The experimenting done by Mr. Wallace with arc lamps and with other kindred apparatus would fill a volume. The great electro-magnets made for West Point and for the Stevens Institute of Technology were of his construction. Another branch of work carried out by Mr. William Wallace with his brother, Thomas, was the construction and operation of a huge electro-deposition plant for making the compound copper-plated steel wire used by the Postal Telegraph Company between New York, Washington, Chicago and St. Louis for Elisha Gray's harmonic telegraph. In these baths over 100 miles of steel wire was treated at the time. Mr. Wallace was himself very much interested in electrical history and development and was a collector of its relics and literature. He was a delightful man to know.

EDUCATIONAL.

CASE SCHOOL OF APPLIED SCIENCE.—The inauguration of Dr. Chas. Sumner Howe as president of Case School of Applied Science, of Cleveland, Ohio, was held in that city May 10 and 11. The inaugural exercises were attended by more than a hundred delegates from over seventy-five leading colleges, technical schools, universities, engineering societies and scientific journals. Euclid Avenue Congregational Church, where the exercises were held, was filled to overflowing. Dr. Worcester R. Warner, representing the Board of Trustees, made the opening address and was followed by President Henry Churchill King, of Oberlin College; President Ira Remsen, of Johns Hopkins University; President H. S. Pritchett, of the Massachusetts Institute of Technology; Mr. John R. Freeman, of the American Society of Mechanical Engineers, and President Charles F. Thwing, of the Western Reserve University. In his inaugural address Dr. Howe spoke on "Does a Technical Course Educate." After an informal luncheon the Case School Laboratories and Shops were opened for the inspection of delegates. An inauguration banquet was held at the Hollenden Hotel in the evening. Case School of Applied Science is one of the most progressive and best equipped technical schools in the Central West. It was founded by Leonard Case, Feb. 24, 1877, and the present school was opened for instruction September 15, 1881. At the inauguration exercises it was announced that Mr. John D. Rockefeller had presented the school with $200,000 to be used in improving its facilities.

PERSONAL.

E. H. DAVIS.

MR. ERNEST H. DAVIS, whose portrait we present herewith, was elected president of the National Electric Light Association at Boston last week, as already noted in these pages. Mr. Davis was born in Philadelphia Nov. 13, 1859. He was educated at the public schools of that city and was admitted to practice at the bar. He had always had a taste, however, for industrial and transportation enterprises, and, after securing some railroad experience, became, in 1894, connected with the Lycoming Electric Company and the Williamsport Passenger Railway Company, of Williamsport, Pa. More latterly he became associated with the Edison Electric Illuminating Company and remains active in the management of all these various enterprises. For the last few years, Mr. Davis has filled with remarkable success and efficiency the secretaryship of the Association. Each incoming president has found in him an official posted as to its affairs and enthusiastic for its advance, and the Association has never enjoyed greater prosperity and growth than during the term of Mr. Davis' incumbency. In a post of responsibility and delicacy he has made innumerable friends by his tact, energy and kindly disposition, and his election to the presidency, while quite unexepected, has been hailed everywhere with marked approval.

D. FARRAND.

MR. DUDLEY FARRAND, the new secretary of the National Electric Light Association, whose election to that position was gazetted in these pages last week, is prominently known in the electric light affairs of the State of New Jersey, where he was born at Bloomfield in 1869, a member of the old Farrand family of that State, Michigan and Pennsylvania. After education in the Bloomfield public schools he attended the Newark Academy, graduated in 1887, and then entered Princeton University for the class of '91, but owing to circumstances beyond his control was compelled to abandon his college plans. He then became connected with the Newark Electric Light and Power Company, and with Mr. P. N. Jackson was one of the mainsprings of that large enterprise. While still a young fellow of only twenty-one, he was made a director in the company, and given responsibility for a large part of the work. In 1896 he was made assistant general manager of the People's Light and Power Company and general manager in 1897, controlling directly all the concerns which constituted the People's Light and Power Company. In the spring of 1899 the United Electric Company of New Jersey was formed, of which again Mr. Farrand became general manager, with a territory including several counties of the State, and embracing latterly scores of municipalities. More lately the Public Service Corporation of New Jersey consolidated the lighting enterprises of that region, with the street railway enterprises, and Mr. Farrand has again continued in the direction of that entire department, which embraces also the generation of current for a large trolley network. Mr. Farrand is a man of considerable public spirit, and outside his official connection with other electrical enterprises is a member of the American Institute of Electrical Engineers and of the American Society of Mechanical Engineeers. While his leisure is limited, his nearness to New York will enable him to give a good deal of time to the duties of the office, which will still be carried on directly under the active and highly efficient charge of Miss Harriet Billings, assistant secretary.

MR. W. K. PALMER, M. E., consulting engineer, Kansas City, Mo., has removed his office from 402 Lyceum Building to 718 Dwight Building.

MR. G. B. LELAND, who was formerly with the Norwich, Conn., Gas & Electric Company, has assumed the management of the Stamford, Conn., Gas & Electric Company.

MR. S. R. BOTTONE has written for Macmillan Company a pamphlet all about radium, which they have recently issued. It deals with the properties and uses of the new "element."

MR. MARK A. REPLOGLE, having very recently perfected his new differential water-wheel governor, has been retained by the Replogle Governor Works as chief engineer, and the manufacture and sale of this new machine will begin at once.

MR. GEORGE GREENWOOD, for several years resident engineer of the Jalapa Railway & Power Company, Mexico, has been appointed to represent the interests of the General Electric Company on the Pacific coast of the Southern Republic.

MR. J. G. SPLANE, president of the Pittsburgh and Allegheny Telephone Company, writes to the effect that he is not responsible for the recent public utterances attributed to him as to an impending big independent telephone consolidation.

J. B. ALLAN.

MR. JOHN B. ALLAN, formerly vice-president and general manager of the Allis-Chalmers Company, will shortly commence his duties as Western manager of the Westinghouse Machine Company with headquarters at 171 LaSalle Street, Chicago, having direct charge of entire Western district. Mr. Allan has been prominently associated with the Allis-Chalmers Company for the past twenty-four years and has filled positions of progressively increasing importance, including those of sales manager, general manager and vice-president. Mr. Allan was born in 1860 at Davenport, Ia., and received a common high school education in his native city, followed by a course at the Wooster Polytechnic Institute, from which he graduated in 1880 as a mechanical engineer. He immediately commenced practical work, entering the service of the Edward P. Allis Company, shortly after leaving college, wherein he was successively employed as draughtsman, machinist and erecting superintendent. During this time, Mr. Allan also had charge of making economy tests of engine and steam plants. In January, 1895, the company opened a general sales office in Chicago, of which Mr. Allan was made manager, the engineering as well as the selling departments coming under his supervision. Mr. Allan's subsequent career has been one of continuous advancement, and his wide acquaintance and popularity in the field to which he has devoted his main efforts peculiarly fit him for assuming his new duties in this same field. He is a prominent member of the American Society of Mechanical Engineers and the Engineers' Club of New York.

MR. C. O. BAKER, president of Baker & Company, of Newark, N. J., and New York City, N. Y., the well-known refiners and artisans in platinum, gold and silver, sailed on Wednesday, May 18th, on the White Star steamship *Cedric*, for his annual trip abroad.

MR. J. B. WHITE, of the British electrical engineering and contracting firm of J. G. White & Company, Limited, London, is to be married early this month. The bride will be Miss Harriet Stevens, of Brooklyn. The ceremony will take place in the British metropolis.

MESSRS. T. F. MANVILLE, president of H. W. Johns-Manville Company, New York, E. B. Hatch, president of Johns-Pratt Company, Hartford, and J. W. Perry, manager of the electrical department of the former company, sailed for England on April 26th and will return about June 10th.

MR. J. W. F. BENNETT, formerly associated with the Thompson-Starrett Company, has been appointed to a responsible position in the new building department recently established by the electrical engineering and contracting firm of J. G. White & Company, Limited, of London, England, under the management of Mr. R. A. Denell, lately manager of the D. H. Burnham Company, of Chicago, Ill.

DR. ELVIO SOLERI, assistant to Prof. Morelli, professor of machine design at the Museo Industrialeo of Turin, has arrived in the United States and will represent the Italian government at the World's Fair in the capacity of technical delegate. Dr. Soleri will also represent at the Fair the Museo Industrialeo, two Italian technical journals, and make reports to several important Italian manufacturing companies on technical exhibits.

MR. FRANCIS S. THAYER, superintendent of the Westerly Gas & Electric Light Company, has been selected as superintendent of the Norwich, Conn., municipal lighting plant, by the board of commissioners. He was for 13 years with the Narragansett Electric Company, nine years of which period he was superintendent of their gas and electric plants at Warren and Bristol. Mr. Thayer is about 37 years of age. He is succeeded at Westerly by Mr. F. N. Clark, who has been with the plant there for seven years past.

MR. G. MARCONI made recently an interesting statement to the *Wall Street Journal*, resuming his recent work, especially with regard to the proposed system of marine news on the Atlantic. He said also: "The Italian government has detailed an officer of the navy to attend the St. Louis Exposition, and there give an account and exhibit of the long distance work accomplished on the voyage of the *Carlo Alberto*. He will have with him the original messages, the tape and the records. On that voyage we transmitted messages to Poldhu, to Kronstadt, Russia; Naples and Spezia, Italy, and to Cape Breton. He has been instructed to thoroughly explain to representatives of the American government the results of our experiments on that voyage."

MR. ARTHUR WEST, formerly engineer with the Allis-Chalmers Company, has joined the staff of the Westinghouse Machine Company as chief engineer, with headquarters at East Pittsburg. Mr. West is eminently fitted for his new position by his experience with the Allis-Chalmers Company, with whom he has been associated for about seventeen years in various positions. For several years past he has had full charge of their entire pumping station work. Mr. West was born at Milwaukee, Wisconsin, in March, 1867, and received a common school education at Milwaukee public schools, supplementing this by a technical course at the University of Wisconsin, from which he graduated in the class of 1887. This was followed by post-graduate work at the same institution, and he then entered the employment of the Edward P. Allis Company as a machinist, and his career with that concern has been one of continuous advancement. Some of the positions which he has filled are those of erecting engineer, assistant to shop superintendent, assistant superintendent, private engineer for Edwin Reynolds in his special work, general trouble engineer on all steam engine work, salesman in pump department, engineer of tests, manager of pump department, and finally assistant chief engineer. He is a member of the American Society of Mechanical Engineers and the Engineers' Club, of New York. Mr. West recently started for Europe to investigate the most recent practice of British and Continental engine builders.

Trade Notes.

THE J-E-M SHADE-HOLDER COMPANY has removed its office from 503 Fifth Ave., to 13 East Thirtieth Street, New York.

THE WESTINGHOUSE ELECTRIC & MFG. COMPANY has opened a sub-office at Room No. 1110 Hibernia Bank & Trust Building, New Orleans, La.

HOTEL TELEPHONES.—The Lambert Schmidt Telephone Mfg. Company, Weehawken, N. J., has just shipped a 270-drop central energy switchboard and telephones to the Grand Hotel at Grand Hotel Station, N. Y.

STANDARD TELEPHONE & ELEC. COMPANY, of Milwaukee, has removed its offices and factory from Madison to that city to secure better facilities generally. It has most advantageous quarters at Michigan and Jefferson Streets, with larger plant and new machinery.

AMERICAN STONE CONDUIT COMPANY, of 94 LaSalle Street, Chicago, has issued a neat little brochure as to stone pipe for underground conduits. It describes and illustrates a large variety of work for electrical purposes, and shows how the thing is done, in general and in detail.

THE ELECTRIC APPLIANCE COMPANY, Chicago, is advertising as headquarters for heating apparatus and is claiming that the central stations may make one blade of business grow where none grew before by pushing such appliances. There is a good deal of truth in this assertion.

NERNST LAMPS.—A recent publication of the Nernst Lamp Company is a handsome little pamphlet entitled "44 and 55-watt Nernst Lamps for Alternating-Current Circuits." Some excellent illustrations show the details of the lamp, which is of the single-glower, helical-heater type.

TEMPERING AND ANNEALING FURNACE.—F. W. Braun & Co., Los Angeles, Cal., have issued a pamphlet devoted to the Braun portable forge and tempering furnace which contains some excellent practical information on the subjects of annealing, tempering and case-hardening of value to those interested in these processes.

ONE FAD in electric lighting is to take advantage of the decorative effects possible with the Packard Zenith lamps. The rush of business at the present time is partly the result of orders for dining-room, pavilion and porch lighting at summer resorts. The Electric Appliance Company, Chicago, general western agents, has special circulars on these lamps.

DUNCAN METERS.—The latest bulletin of the Duncan Electric Mfg. Co., Lafayette, Ind., is devoted to the Duncan integrating wattmeter for direct currents, which is illustrated by excellent cuts showing every detail. Among the points brought out especially are the new means employed for friction compensation, the visual bearing and non-oxidizing commutator.

COLUMBIA INCANDESCENT LAMP CO., St. Louis, Mo., has issued in very neat and tasteful form a little brochure entitled "A Wallet Full of Wisdom." It is made up in wallet form as to cover, and the contents deal with the qualities of the Columbia lamp. Views are given of various departments of the factory, and there are illustrations also of different types and sizes of lamps.

FAIRBANKS, MORSE & COMPANY, Franklin and Monroe Streets, Chicago, have just issued their pumping machinery catalogue No. 480. It represents marked and consistent advance and improvement in pump design, and shows apparatus competent to fill the wants of a wide range of users in the field of power equipment, etc. Copies of this valuable catalogue can be obtained upon application by all interested.

PERKINS POWER PRESSES are the subject of a handsome and elaborate catalogue issued by the Perkins Machine Company, of Warren, Mass. It has an ornamental cover in stiff boards, and its 176 pages embrace a large variety of presses, which are shown in all their details, many of the products being also exemplified. The descriptions are in many instances full and elaborate to a degree, and specifications are also given.

WORLD'S FAIR LITERATURE.—The Electric Controller & Supply Company, Cleveland, Ohio, has prepared for distribution at the World's Fair nine bulletins describing some of its more important specialties, namely, magnetic switches and clutches, lifting magnets, solenoids and electromagnets, controllers, brakes, resistance units and electrical fittings. The pamphlets are bound in tinted covers, presenting an unusually attractive appearance.

THE ELECTRIC STORAGE BATTERY COMPANY, of Philadelphia, has taken a residence at 4472 Forest Park Boulevard, St. Louis, for the use of members of its staff attending the Louisiana Purchase Exposition. The Company's exhibit, which is the largest and most comprehensive that has ever been made by a storage battery company, is practically complete. It contains many interesting features, showing the recent developments in storage battery practice.

THE JOHN H. McGOWAN COMPANY, Cincinnati, Ohio, reports a brisk trade, especially in the municipal work. It now has on its books orders for pumping machinery aggregating a total of nearly 100,000,000 gallons capacity, from the following cities: Ottawa, Ohio; Vermillion, Ohio; Johnstown, Ohio; Murray City, Ohio; Bardstown, Ky.; Pemberton, S. C.; Winston-Salem, N. C.; Kinston, N. C.; Hawkinsville, Ga.; Dalton, Ga.; Winona, Miss.; Columbus, Miss.

HAZARD MFG. COMPANY, of Wilkesbarre, Pa., has now headquarters at 71-73 West Adams Street, Chicago, and Mr. Robert H. Peet, who for three years past has had charge of the sale of insulated wires and cables made by the concern, has been made sales agent for its entire product in Chicago and Western territory. With him will be associated as assistant Mr. Homer A. Wessel, Jr., from the factory. A large stock will be carried. The Hazard products have a fine reputation in the West.

FREDERICK PEARCE, 18 and 20 Rose Street, New York City, has just issued catalogue No. 11 on telegraph and electrical apparatus and supplies. It is very complete in all the departments of telegraphy, telephony, light and power, giving special attention to the Pearce specialties in knife switches, panel boards, etc. A number of views of the offices and factory are given, and the 377 pages are profusely illustrated. It is altogether a handsome and useful publication for the industry and trade.

THE F. BISSELL COMPANY, Toledo, Ohio, builders of switchboards for lighting and power, reports that its trade in these boards has increased so largely that it has become necessary to extend its facilities and that it has recently placed large orders for additional stocks of marble and slate. The Bissell Company has found such a large demand for information on its switchboards that it has prepared a new handbook on switchboards which will be sent free of expense to anyone interested in switchboards.

THE METROPOLITAN ELECTRICAL SUPPLY COMPANY has settled in its new building, 184 Lake St., Chicago. Its prominent location and its fine new store and sales room, with increased shipping facilities enable it to take care of a largely increasing business with very much better satisfaction to customers. This company must be reckoned as a factor in the electrical supply business. Its customers are found all over the country and in foreign lands. It has quite a line of first-class specialties such as Eureka flexible conduit, Toerring arc lamps, Shedd oscillating fans, etc., etc. It is carrying a very large stock of general supplies and is increasing its line constantly by putting in new specialties as fast as perfected.

DOUBLEDAY-HILL ELECTRIC COMPANY, Pittsburg, Pa., has issued in its general catalogue No. 4 of electrical supplies one of the most comprehensive volumes as to electrical apparatus given to the trade of late years. It is a massive volume of 1068 pages printed on good paper in clear type and profusely illustrated with cuts of every class of electrical apparatus for which there is a market. This apparatus does not merely include the smaller varieties of electrical supplies, but ranges into the larger material, such as generators and motors, and includes even gas engines. The information given is well classified and is remarkably complete and specific, including sizes, prices, code words, descriptive matter, etc. In some of the instances the text is very full and useful. The owner of this catalogue is fortunate. To see it is to want it, and to obtain it means daily use for any busy central station manager, superintendent of isolated plants, telephone man or telegrapher.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED MAY 24, 1904.

[Conducted by Rosenbaum & Stockbridge, Patent Att'ys, 140 Nassau St., N. Y.]

758,701. ELECTRIC BURGLAR AND FIRE ALARM; Solomon Schwarzchild, Rochester, N. Y. App. filed Feb. 24, 1902.

759,237. CIRCUIT CHANGER; Charles C. Cadden, Cleveland, Ohio. App. filed June 15, 1903. (See page 1088.)

759,796. LIGHTNING-ARRESTER; John C. Barclay, New York, N. Y. App. filed Sept. 9, 1903. (See page 1088.)

760,399. SELECTIVE SIGNAL SYSTEM; Fred C. Penfield and Olin Templin, Lawrence, Kan. App. filed March 17, 1902. (See page 1088.)

760,426. ALTERNATING CURRENT WATTMETER; Frank Conrad, Edgewood Park, Pa. App. filed Feb. 20, 1903. The meter is provided with two quadrature adjusting coils connected together in parallel and means for transferring resistance from the circuit of either of said coils to that of the other.

760,480. SYSTEM OF ELECTRICAL DISTRIBUTION; John S. Peck, Pittsburg, and Joseph W. Farley, East Pittsburg, Pa. App. filed July 3, 1903. Means for varying and regulating the voltage delivered to the three-phase side of a system in which transformers are employed for transforming two-phase energy into three-phase energy.

760,539. PROCESS OF RECOVERING METALS FROM ORES OR SANDS; William J. Jory and Joseph H. Jory, San Francisco, Cal. App. filed April 7, 1903.

760,549. PLUG AND SPRING JACK SWITCH; Frank B. McBerty, Evanston, Ill. App. filed Jan. 6, 1900. Improvements in the details of construction.

760,554. MANUFACTURE OF SULFID OF ALUMINUM AND ALLOYS OF ALUMINUM; Miyagoro Onda, Nagoya, Japan. App. filed Oct. 14, 1903.

760,556. MOTOR CAR; Alexander Palmros, Columbus, Ohio. App. filed Sept. 5, 1900. An electric locomotive in which the side frames are chambered out to accommodate the wheel-suspension devices.

760,561. PROCESS OF MANUFACTURING HARD POROUS ELECTRODES FOR BATTERIES; Heinrich Paul Rudolf Ludwig Porske and Gustav Adolph Wedekind, Hamburg, Germany. App. filed Nov. 18, 1903.

760,565. ELECTRICAL SWITCHING APPARATUS; Walter J. Richards, Milwaukee, Wis. App. filed April 29, 1903. Details in the switching apparatus for stopping and starting the motor driving an air compressor.

760,568. ELECTRIC INDICATOR; Edward Sadler, Upper Tooting, England. App. filed May 16, 1903. An annunciator in which a disk previously set is restored upon the sending of another signal to operate a different disk.

760,573. TELEPHONE-EXCHANGE SYSTEM; Charles E. Scribner, Jericho, Vt. App. filed Sept. 15, 1902. (See page 1088.)

760,574. ELECTRIC POLE CHANGER; Charles E. Scribner, Jericho, Vt. App. filed Sept. 15, 1902. A pole changer for ringing current in telephone exchanges arranged so that a resistance will be included in the circuit at the time contacts are broken, to prevent sparking.

760,577. CLUTCH MECHANISM; Severn D. Sprong, New York, N. Y. App. filed Oct. 29, 1903. A magnetic clutching apparatus automatically ensuring a moderate advancing movement of a planer and the automatic reversal and more rapid return movement.

760,591. FAN MOTOR SUPPORT; Ernest P. Warner, Chicago, Ill. App. filed Sept. 8, 1902. A construction of ball and socket joint whereby the motor and fan can be set at any angle.

760,598. POLE CLAMP OR COUPLINGS; Clyde B. Wynegar, Greenwood, Ind. App. filed March 7, 1904. A coupling for a trolley pole, permitting the latter to be twisted, so as to bring the wheel into the plane of the wire.

760,601. HIGH TENSION OIL SWITCH; Henry P. Ball, New York, N. Y. App. filed Feb. 25, 1902. A switch designed for safely handling high tension, large quantity currents and which under ordinary conditions of service will not be injuriously affected by the arc produced upon breaking the circuit or if injured by an excessive arc, may be readily and quickly repaired.

760,602. OIL SWITCH; Henry P. Ball, New York, N. Y. App. filed March 10, 1902. Consists essentially in locating in separate insulated oil-wells, the terminals of a conductor forming a leg of a polyphase distribution system.

760,603. ELECTRIC SWITCH; Henry P. Ball, New York, N. Y. App. filed July 5, 1902. Improvements in various features of construction, the mechanism for controlling the switch from a distance and the mechanism for shifting the circuit connections of the switch slightly before the opening or closing of the switch.

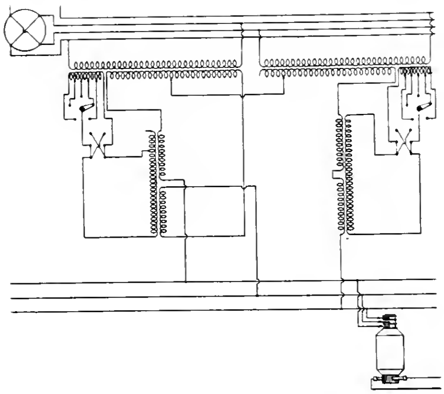
760,611. PRINTING TELEGRAPH RECEIVER; George A. Cardwell, New York, N. Y. App. filed April 11, 1903. General improvements in page printers.

760,620. INSULATOR BRACKET; Francis J. Grant, Chicago, Ill. App. filed Aug. 15, 1903. Details.

760,641. TROLLEY POLE; Alfred W. Morgan, Longbeach, Cal. App. filed Nov. 16, 1903. Details.

760,643. THIRD RAIL GUARD FOR ELECTRIC RAILWAYS; Vincent M. Newman, Bayside, N. Y. App. filed Feb. 16, 1904. The plow enters a slot in the guard to engage the third rail and sections of one side of the guard are hinged to permit the removal of the plow when necessary.

760,656. ELECTRIC TRACK SWITCH OPERATING MECHANISM; Charles W. Squires and James B. Squires, Springfield, Mass. App. filed Jan. 20, 1903. Supplemental switch mechanism for determining which of a pair of solenoids shall be energized to actuate the switch tongue.



760,480.—System of Electrical Distribution.

760,657. PORTABLE ELECTRIC HAND LAMP; George Stein, New York, N. Y. App. filed July 18, 1903. A cylindrical casing containing battery and lamp with details of a circuit controller.

760,679. CIRCUIT BREAKER; John Burry, Ridgefield Park, N. J. App. filed Aug. 30, 1902. A telegraph line circuit breaker consisting of two springs under tension to press normally against each other, an electromagnet for operating one spring to open the circuit and a pointed key past whose point the circuit may be remade or be broken by operating the key.

760,711. AUTOMATIC TELEPHONE SYSTEM; James C. Slater, St. Louis, Mo. App. filed March 10, 1902. (See page 1088.)

760,712. STORAGE BATTERY PLATE; Edward Wanton Smith, Philadelphia, Pa. App. filed Sept. 10, 1903.

760,713. AUTOMATIC REGULATOR FOR ELECTRIC GENERATORS; William A. Turbayne, Lancaster, N. Y. App. filed Sept. 8, 1903. In railway car lighting where the dynamo is driven from the axle, the dynamo is mounted upon a carriage to be adjustable bodily for altering the tension of the belt. The carriage is moved automatically and also by hand when necessary.

760,714. SYSTEM OF ELECTRICAL DISTRIBUTION; William A. Turbayne, Lancaster, N. Y. App. filed Nov. 2, 1903. Improvements for automatically varying the strength of the field of the dynamo to regulate its output, in a car lighting system.

760,736. TROLLEY POLE HEAD; John E. Greenwood, Utica, N. Y. App. filed Sept. 25, 1903. Two wheels mounted in tandem on independent pivoted frames.

760,737. SAFETY CLAMP FOR RAILS; Thomas J. Harleman, Packerton, Pa. App. filed March 28, 1904. A bar having special connecting clamps at each end for electrically bridging the rails of a railway when safety signals are to be set.

760,740. MEANS FOR SAFELY CONDUCTING ELECTRICAL CURRENTS; Edward A. Jarvis, Port Richmond, N. Y. App. filed Dec. 16, 1903. A third rail is housed in a conduit having a sectional metal roof and connecting armatures are arranged to be moved by a magnet on the vehicle, so as to connect the rail with the roof, whence the current is taken by the shoe.

760,787. ELECTRIC MAIL AND PACKAGE CARRYING DEVICE; Edward G. Hamilton, Richmond, Ind. App. filed July 28, 1902. An electric mail and package carrying device adapted to travel automatically in either direction upon a pair of track wires.

760,794. ELECTRICAL BATHING APPARATUS; Robert S. Lawrence, Boston, Mass. App. filed Aug. 3, 1903. The tub is provided with electrodes so placed as to direct the current through the body of water.

760,798. CIRCUIT BREAKER; Andrew C. Miller, Corona, Cal. App. filed May 19, 1902. Details of a device intended to give a signal when the rotation of a shaft ceases.

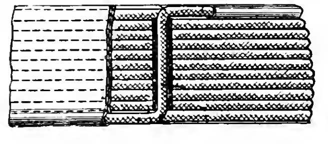
760,801. AUTOMATIC TROLLEY CONTROLLING DEVICE; Horace W. Nichols, Philadelphia, Pa. App. filed Sept. 1, 1903. A winding drum and ratchet arrangement controlling the cord.

760,810. MOTOR VEHICLE; Semple S. Scott, St. Louis, Mo. App. filed Aug. 5, 1903. A chair or small vehicle electrically operated and provided with means for stopping the motor automatically in case of a collision with any object.

760,813. ELECTRIC PRINTING MACHINE; David G. Smyth, Hartford, Conn. App. filed Feb. 16, 1903. Details.

760,815. ELECTRIC SWITCH; Frank Stevens, Philadelphia, Pa. App. filed Dec. 30, 1903. A two-button push switch contained in a box adapted to be set flush in the wall.

760,822. CLUTCH; Walter S. Timmis, Brooklyn, N. Y. App. filed Dec. 9, 1902. A clutch used in connection with a machine for producing, assembling or printing a line of characters; the clutch automatically disconnects the driven shaft from the main shaft at the end of each line, whereby the mechanism for printing will be at rest during the return of the paper carriage to commence a new line.



761,039.—Insulation for Transformer Coils.

760,828. TROLLEY; John S. Weckman and Robert J. Millard, Carnegie, Pa. App. filed Oct. 17, 1903. Details.

760,846. ELECTRIC RAILWAY SWITCH; Rupert L. Border, Pittsburg, Pa. App. filed Oct. 15, 1903. Details.

760,850. BLOW OUT CHUTE; Fred B. Corey, Schenectady, N. Y. App. filed Oct. 16, 1902. Metal plates contained within a passage in which the fuse is located are magnetized by the current traversing the fuse and furnish a field to destroy any arc that might form on the blowing of the fuse.

760,895. ELECTRIC CLOCK STRIKING MECHANISM; Emil Meyer, Swissvale, Pa. App. filed Sept. 24, 1903. Details.

760,897. STORAGE-BATTERY PLATE; Achille Meygretm, Paris, France. App. filed June 29, 1903.

760,947. ELECTRIC BOND FOR RAILWAY RAILS OR OTHER CONDUCTORS; John S. Alexander, New York, N. Y. App. filed Feb. 25, 1903. Two recesses in the abutting ends of the rails together form a chamber having a contracted opening at the surface of the rail; a spreader is placed in the chamber and a forked conductor is then driven through the narrow opening and forced into good contact with the rails by the spreader.

760,955. ELECTRIC SIGNALING SYSTEM AND APPARATUS EMPLOYED THEREIN; Robert G. Callum, Washington, D. C. App. filed Oct. 11, 1902. The object is to automatically notify central office of the breakage of a spring in any of the signaling instruments.

760,970. MEANS FOR CONTROLLING ELECTRIC CURRENTS; Isidor Deutsch, Montreal, Canada. App. filed April 30, 1902. Improvements in various features of a train lighting system.

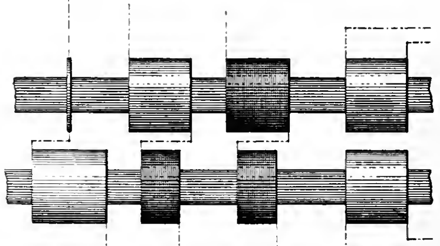
760,976. ELECTRIC SIGNAL SYSTEM; Otto Ernst, Larchmont, N. Y. App. filed Sept. 22, 1903. Details.

760,988. ELECTRICALLY CONTROLLED SWITCH; William H. Hillyer, Atlanta, Ga. App. filed Jan. 21, 1903. Details of the circuit mechanism whereby the car automatically takes current from the trolley wire to actuate the magnets which control the switch tongue.

761,000. TROLLEY; James A. Lavery, New York, N. Y. App. filed Nov. 7, 1903. Two spring-actuated guard-fingers for retaining the wheel upon the wire are controlled by a cord.

761,003. CONTROLLING MEANS FOR ELECTRIC CIRCUITS; Julius K. Lux, St. Louis, Mo. App. filed June 25, 1903. Details.

761,012. AUTOMATIC REGULATOR FOR ELECTRIC GENERATORS; Marcellus R. Shedd, Lancaster, N. Y. App. filed Sept. 8, 1903. Improvements in the regulator described in U. S. Patent 705,487.



12,223.—Alternating Current Transformation.

761,026. CALL BOX; John C. Barclay, New York, N. Y. App. filed Jan. 27, 1904. The object is to adapt ordinary messenger call boxes for use both as alarm boxes and as watchman signal boxes; this is done by a simple attachment to the call box.

761,029. APPARATUS FOR THERAPEUTICAL PURPOSES; Fred H. Brown, Los Angeles, Cal. App. filed March 28, 1904. A belt having two or more electrically energized vibrators relatively attuned to give off harmonic vibrations to the body of the wearer.

761,039. INSULATION FOR TRANSFORMER COILS; Charles Le G. Fortescue, Wilkinsburg, Pa. App. filed Sept. 29, 1903. The lead at the end of one layer which passes across the turns to begin the next layer, is inclosed in an insulating sleeve.

761,044. METHOD OF PURIFYING WATER; Virgil M. George, Youngstown, Ohio. App. filed Jan. 8, 1904.

12,223. ALTERNATING CURRENT TRANSFORMATION; Maurice Hutin and Maurice Leblanc, Paris, France. App. filed April 20, 1904. A method of generating electrical energy which consists in producing two separate alternating magnetic fluxes in quadrature and generating by the inductive influence of these fluxes three or more alternating working currents, dephased with reference to each other.

GOVERNMENT AND WIRELESS.

Elsewhere we print a newspaper account of the Government wireless situation at the present moment, which is illuminating as to the bureaucratic spirit that would have full play in case the Government should decide to assume complete control of a coast line wireless service. It appears that four of the cabinet departments has each its pet wireless system; that three of these are in a struggle to obtain control of the coast line service, and that at least one—the Navy Department—demands exclusive control to the elimination of any stations established by private enterprise. The plan of the latter department is, it seems, to divide the coast into zonal districts of 240 miles, yet according to the correspondent, the system which it champions—that of the German Emperor's court jester—is effective over only 70 miles. The pretence put forth—evidently to appeal to the jingo spirit—is that in time of war national defence will demand that the coastwise wireless service shall be under military control, and that this emergency must be provided for through the organization and administration in times of peace of such service on a military basis. That wireless telegraphy will in future wars play a leading part is undoubtedly true, and for that very reason the art should be permitted the freest possible development in order that it may prove of the greatest possible service when called to war duty. That such development would occur under military domination none, we believe, will seriously assert; and assuming that war periods are to continue to be short in comparison with intervening times of peace, the only proper course open is to encourage in every possible way the inventor, and to place no trammels on development through commercial enterprise, the only limitation being such restrictions as the matter of ethereal interference calls for. And the administration of such restrictions as may be necessary on account of this latter feature of wireless telegraphy would undoubtedly come more naturally under the cognizance of the Department of Commerce and Labor than under any of the departments now battling for that privilege. Under conditions of untrammeled development a wireless coastwise service would, in time of peace, grow up normally, and in time of war could temporarily, with its personnel, be turned over to one of the military departments, and give infinitely better service than an organization fostered as proposed. As to the probable result of naval control, we need only point to the humiliating rank the Naval Observatory holds among similar establishments in this country and throughout the world.

NEW SUBMARINE CABLES.

Whatever may be the ultimate results with wireless telegraphy, it is evident that submarine cable managers and promoters are pursuing their way unterrified. The Frankfurter *Zeitung* now announces that German and Dutch capitalists are to do the financing of a cable from the Dutch Island of Menado Tua, off the coast of Celebes, East Indies, to the American Island of Guam, and thence to Shanghai. Through a connection with the American cable, it is intended to eliminate British influence over the German and Dutch cable business with East Asia. A company for laying the cable is being formed. with a capital of $1,750,000, the German and Dutch Governments giving large subsidies. It is also intended to issue a 4 per cent. loan of $1,875,000, which will be taken by the Dresdner Bank, the Schaaffhausen Bank, the Disconto Gesellschaft, and the Darmstaedter Bank of Berlin, and two Dutch banks. This new announcement comes just after the completion of the second cable between this country and Germany, and gives force to our remark as to the apparent indifference of cable people to wireless progress. We do not quite understand all this Teutonic activity in the submarine cable field, but possibly in dull times the cable manufacturers are willing to help push things a bit with the financiers so as to keep their factories employed. There are, of course, political and strategic reasons to be considered and at such a hint is pointed in the advices from Frankfort.

MOTOR DRIVE AND ROPE DRIVE.

Lest our motor friends should think that they are going to have it all their own way in factories under the régime of universal electric power, we venture to call their attention to a challenge which may perhaps jog their complacency and apathy this sultry weather. The cudgels have lately been taken up strongly for rope drive and discussions of the subject by the New England and Southern Cotton Manufacturers' Associations have led to the action to which we now call notice. The American Manufacturing Company, of New York City, manufacturers of transmission rope and other cordage, agrees to furnish the necessary rope sheaves, rope and driven head for the main drives of any cotton or woolen mill in the United States, using 500 or more horse-power, which is developed at the mill site, at one-quarter the price for which any responsible company furnishing electrical apparatus will agree to install the generators, motors, motor shafts, switchboard, wiring and other appliances necessary to electrically transmit the same power. Where the power is generated at a distance, if the mill will install one central motor, the company will agree to distribute the power from the motor to the main line shafts with rope drives for one-half the cost of electrical apparatus to distribute the same power. We confess our utter inability to see how this proposition is going to prove that electric power is not all that is claimed for it, but we should be glad to see the bases upon which such an offer is taken up as economically sound and best—if it is accepted by anybody. Meantime, our motor friends will observe that they still have a good deal of missionary work to do.

OIL FOR INSULATING PURPOSES.

Among the papers read at the recent convention of the National Electric Light Association was one by Mr. C. E. Skinner, entitled as above, which contains an excellent résume of the principal data relating to transformer oil and switch oil. With steam turbines busily engaged in reducing the opportunities for the use of mineral oil, there is comfort for the central station engineer in the reflection that many hundreds of thousands of gallons of oil are being used annually for the insulation of transformers and similar apparatus. If the adoption of electric lighting sets a limit to the classical cry for oil because our lamps have burned out, at least it sets up partial restitution by the modern cry for oil because our transformers have burned out. We must have oil to insulate with, even though we do not have oil to burn. The paper points out two very significant facts in connection with mineral transformer oil, namely, that one-thirtieth of one per cent. of water in the oil markedly reduces the dielectric resistivity, and, moreover, that after one-fifteenth of one per cent. of water is present, the further reasonable increase in the quantity of water does not reduce the dielectric resistivity much further. Thus, according to certain tests cited, a sample of dry oil showed that 9.5 kilovolts were required to disrupt a gap of 75 mils, or 1.9 mm., between brass balls ½ inch, or 1¼ cm., in diameter. The effect of 1/50th of 1 per cent. of water mingled with the oil appears to have brought the disruptive voltage for this gap down to 5 kilovolts, or nearly one-half. On the other hand, about ¼ of 1 per cent. of water only reduced the voltage to 3.6 kilovolts. The moral of this tale is "keep your oil dry", like the old watchword of the flint-lock age, "keep your powder dry."

Fortunately, the heat liberated within transformers when in use promotes evaporation of moisture, and thus tends to maintain high dielectric resistivity. It would seem likely for the same reason that high-tension transformers would be more apt to break down, tensionally, after some weeks or months disuse, when moisture had somehow succeeded in condensing into the oil. The paper also shows how misconceived and erroneous are the ordinary notions concerning the inflammability of oil. The popular idea is that oil is highly inflammable, derived from observations of conditions in which oil is spread out into thin layers, readily capable of being heated to the burning point. In bulk, it is shown that oil is almost like water in its non-inflammability. The author of the paper describes experiments that demonstrate this property, and alludes to a recent case in which a blazing transformer was dropped into an oil tank to put out the fire. This is a case of adding fuel to a flame, too suddenly for the existence of the flame. The paper is both valuable and timely. It would seem that the main dependence of the electrical engineer for insulation in dealing with high tensions must be, among fluids, upon oil and air. Of these oil is incomparably the superior, and air by far the more plentiful. In the buildings, oil is being used. In the transmission lines air is relied upon. The better we can depend upon oil within doors, the better we can face the problems of air out of doors.

EFFICIENCY CURVES OF CONVERTERS.

Prof. A. S. McAllister, in his article printed last week, pointed out that in the ordinary converter the loss of power at any load may be fairly well represented as the sum of a constant or friction term and a variable which is proportional to the square of the load current. On the assumption that this statement of the losses is strictly correct, the efficiency curve with respect to load would be a hyperbola, the maximum point of which would mark the equality between the two terms referred to; i. e., equal constant and variable losses. This result is pointed out as being a close approximation. Nearly all dynamo-electric apparatus is subject to the general rule of having a substantially constant loss, and also a loss increasing with the square of the current. In so far as the proposition is correct, it has been shown that the efficiency curve is an acute hyperbola, with its maximum at equal constant and varying losses, and with the percentage drop in the apparatus equal to half the drop in efficiency below 100 per cent. Even when, owing to secondary effects of loading, the frictional losses do not remain constant, the departure from constancy is rarely so great that advantage cannot be gained in practice from the application of these propositions to the efficiency curve of a machine. For example, if the efficiency curve is still rising at full load, then either the frictional losses may be regarded as unduly heavy, or the I^2R losses are not up to their ordinary magnitude. As a rule, designers aim at making the efficiency a maximum at the average load of operation, and this is often in the neighborhood of three-quarters load.

EXPERIMENTS WITH THE MAGNETIC DETECTOR.

Our esteemed contemporary, *The Physical Review*, is always welcome, and is given an honored place on the shelves we devote to more erudite, but less immediately utilitarian, scientific literature. It is now more welcome than ever, since it has within the last two months adopted the sensible practice of issuing its pages cut. Physics is long and life is short, and no man should be compelled to do badly and laboriously by hand that which a machine can do well and easily by power. To issue a periodical, with pages uncut, is to tempt Providence and the winsome reader not to read. Although the paper knife is bloodless, yet its use excites more profanity than the sword. On page 1120 of our issue this week is an abstract of an article on some experiments by Prof. Arthur J Foley, published in the May number of *The Physical Review*, on the magnetic wave detector. The theory of action of this wave detector is that the Ewing hysteretic diagram is not shaped like a parallelogram, but something like the *f*-hole of a fiddle. The permeability of iron or steel undergoing cyclic magnetization may be defined by the expression, $\frac{d\mathfrak{B}}{d\mathfrak{H}}$ or as the gradient of magnetic flux density, when plotted with respect to magnetic force. When the curve is steep a very small change in magnetic force is accompanied by a large change in flux density; whereas, when the curve flattens, the same small change in magnetic force is accompanied by but a small change in flux density.

If now a primary and secondary winding are associated on an iron core, *small* electric reversals in the primary circuit will set up electric reversals in the secondary circuit, the magnitude of which depends, among other things, upon the permeability of the iron core; for the magnitude of the secondary impulses depends upon the extent of the change of magnetic flux linked therewith, and the greater the permeability of the iron core, the greater will be the flux changes, for a given range of magnetic variation produced by the electric reversals in the primary winding. Consequently, the permeability curve has to be as steep as possible. The Ewing diagram shows that in feeble cyclic magnetizations, the curve of $\mathfrak{B}$ becomes very steep in ascending and descending, near the mean vertical through the center of the diagram. This is the best condition of the iron core for sensitiveness in the transformer. The permeability in this steep and sensitive part of the *f* may be twenty times greater than the average permeability of the iron taken throughout the cycle. Steps must be taken, however, to renew the magnetic youth of the core, at regular intervals, by cyclic demagnetization. The function of the permanent horseshoe magnet is to bring the iron core to the brink of the sudden declivity, and then allow the feeble received electric impulse to push it over the precipice. For this reason the sensitiveness of the transformer rapidly dwindles as the magnetization becomes effected in each reversal. The sensitiveness, on the other hand, is great just when the last polarity is being wiped out and when the iron is nearly passive. Then a little disturbance in the primary coil, with a small resulting variation in $\mathfrak{H}$ will make a relatively large oscillation in $\mathfrak{B}$. All of the observations described in the article appear to be consistent with the above hypothesis.

AUXILIARY BUSINESS FOR CENTRAL STATIONS.

Two of the papers at the recent convention dealt with the much-mooted subject of "side lines" of business for central stations. One of them was an analysis of the results obtained from district heating, the other a suggestion of a new field of endeavor in the manufacture of artificial ice. Last year one of the convention papers dealt with salt works as an auxiliary source of revenue, and there is a steady tendency to study more and more these outlying fields of activity. Broadly, the situation is this: Every central station suffers from inability to utilize fully its investment in the production of its ordinary output, and besides there is in the operation of engines a thermal loss which is present at all loads. The task of dealing with these two conditions is not an easy one, and the conditions themselves are essentially distinct. The heat loss in exhaust steam and in condenser water is one which is greatest at full load, and save in stations with a large load factor, is very difficult to utilize to advantage. The loss by idle investment and by running at uneconomical load falls most heavily on stations with poor load factors, and can be avoided only by forms of utilization which in time do not coincide with the peak. Obviously, if the heat rejected by the engines could be utilized to carry on work which at times of low load could be handled directly from the unused capacity of the plant, the theoretical result would be good; but in practice the very different temperatures of the rejected and the deliberately produced heats hinder their use for a common purpose.

As regards the use of exhaust steam for heating, there is no doubt whatever that its sale is an additional source of revenue which is at times important, but as we have many times remarked, the presence of exhaust steam in an electric plant is in the vast majority of cases irrefutable evidence that electrical energy is being produced uneconomically. Unquestionably, part of the loss may be stopped by selling the steam which ought to have been better utilized in the engines, but we do not believe that it is generally and broadly an economic policy. Under exceptional circumstances, exhaust steam at extremely light pressure or even condenser water can be utilized locally for heating with admirable results. In other cases the local conditions are such that a central heating plant in itself would pay a fair return upon the investment required, and under these circumstances an electric plant can utilize its spare boiler capacity to some advantage, though as a rule the boilers fitted for use with modern high-pressure engines do not work to the best advantage for heating alone. Each plant must work out its own salvation in its own place and way as regards these heating problems. The one common error to be avoided is the supposition that exhaust steam costs nothing to speak of, and that a little back pressure is of no account. If the manager of a station with first-class condensing engines will cut out the condensers, choke the exhaust and then do a little work with the indicator after inviting in a few non-condensing friends, he will do a good bit of missionary work. Where the fuel and other costs are such that there is but little saving in condensation, exhaust steam may be worth more for heating than for power.

To our mind the auxiliary business which utilizes the spare capacity of a plant without injury to the efficiency of power production is far more interesting and satisfactory. The practical problem is as follows: A given plant being unable to build up its load factor beyond a certain point, to what uses can it apply its spare capacity taken at the times and in the amounts in which it becomes available? Clearly, the use must be discontinuous or at least not essentially steady in its demands for power, as otherwise there will be trouble at the peak. And also the business thus taken up should require power if possible all the year round with a maximum in summer. The ice plant as suggested in Mr. Wakefield's paper meets these conditions rather well. In the warmer parts of the country there is a fair demand all the year round, but most in summer when the lighting load is small. Also, if the process be properly worked, the call for power may be very greatly reduced over the peak of the load or even temporarily suspended. Search should be made for other lines of business which can be worked during hours of light electrical load without too serious investment. Any simple business in which there is a large demand for power can be profitably utilized if it can be kept clear of the peak of the load. It is even conceivable that a station able to furnish power cheaply might operate a manufacturing process with a working day deliberately arranged to begin abnormally early and to close before the peak. In fact, in Montreal this latter condition has been realized during the winter months in connection with electric power supply to factories. Certainly, it could often afford to give unusual inducements to a customer who would agree thus to arrange his hours of operation. Water power plants whose cost of operation varies very little with the load could build up their load curves in this way to great advantage, and might get material aid from industries which, like certain electrochemical ones, must get power cheaply and use it in large amounts.

A. I. E. E. High Tension Transmission Meeting.

As previously noted in these columns, a special meeting of the American Institute of Electrical Engineers will be held at Chicago June 21 and 22, the proceedings of which will be confined to a consideration of subjects relating to high-tension electric transmission. The meeting will be conducted by the Transmission Committee, of which Mr. Ralph D. Mershon is chairman, assisted by the Chicago branch of the Institute. There will be a morning and afternoon session each day. Six papers, or introductions to discussions, are on the programme, which will be considered during three of the four sessions. At the fourth session the Committee on Transmission Data will report, and there will be a general discussion on the topics presented at the meeting. The papers are printed in the May issue of the *Transactions* of the Institute, and it is requested that contributions for the discussion of the same be mailed to Mr. Ralph D. Mershon, 29 Broadway, New York, so that they may be received not later than June 17, 1904.

Mr. W. G. Carlton will contribute a paper entitled "Protection of Cables from Arcs Due to the Failure of Adjacent Cables." The paper refers particularly to the protection of cables operated at from 5,000 to 15,000 volts, these nearly always being three-conductor cables. One method of protection noted is to wrap the cables with asbestos paper or tape about one inch thick, using two layers and binding on the asbestos by means of steel or brass tape, which is applied either in an open spiral, leaving an inch or more between the turns, or with edges touching, leaving no open space. While this protection has been found adequate by several large companies, its life is uncertain on underground work and a disadvantage is that heat is less easily radiated on account of the asbestos covering. Another method of protecting cables consists in providing separate chases or runaways for them, and a third method consists in the use of a covering of vitrified clay tile. All of these methods apply more particularly to protection of cables outside of ducts. The experience of one company in Chicago has been that nearly all the trouble on high-pressure cables has been due to defective joints, moisture in the cables near the joints or to sharp bends in the cable. Some burn-outs have occurred due to the lead sheathing of the cables being damaged by electrolysis, but trouble from this source can be prevented by grounding the sheathing at intervals.

Mr. B. G. Lamme contributed a paper entitled "The Synchronous Motor for Regulation of Power Factor and Line Pressure." The conclusions of the paper are as follows:

1. A synchronous motor can be used to establish leading or lagging currents in its supply system by suitable field adjustment, and can thus affect or control power factor or phase relations of the current in the alternating-current system. 2. A synchronous motor will set up leading or lagging currents in its supply system if its field strength is held constant, and the pressure of the supply system is varied above or below that generated by the synchronous motor. Such leading or lagging currents in the supply system will tend to vary the pressure of the system. A synchronous motor can thus act as a regulator of the pressure of its supply system. 3. This regulating action is greatest with synchronous motors, which have the closest true inherent regulation (as indicated by high field magnetomotive force compared with the armature magnetomotive force) in distinction from machines which have close apparent regulation obtained by saturation of the magnetic circuit. 4. If the synchronous motor is used both for regulating the power factor for neutralizing the effect of other apparatus on the circuit, and for regulating or steadying the pressure of the supply system, its normal capacity for regulating will be diminished. 5. The most suitable speeds for best electrical conditions will in general be considerably below highest possible speeds as limited by mechanical conditions. 6. Heavy dampers will increase the effectiveness of the regulating tendency. 7. If the synchronous motor can be used for power purposes as well as for regulation, its apparent capacity is increased. This is due to the fact that the regulation is obtained by means of a wattless component and the power from the energy component, and the algebraic sum of these two is greater than their resultant which fixes the current capacity of the machine. 8. Synchronous converters in general are not suited for regulating the pressure or controlling the power factor for an alternating-current system. 9. The cost of synchronous motors for regulating purposes will, in general, be lower than for alternating-current motors or generators of customary speeds, and will approach more nearly to turbo-generator practice.

In a paper entitled "Long Spans for Transmission Lines," Mr. F. O. Blackwell considers the subject under the heads of cost of towers, strength of conductor, elasticity, strain in conductors, sag of wire, height of towers, insulators and pins, cross arms and construction of towers. The paper includes span and sag curves for aluminum and copper wire.

Mr. M. H. Gerry, Jr., in a paper, will discuss the conditions of continuous service over lines operated in parallel, under the heads of normal operating conditions and accidental conditions. Since little work can be done on high-pressure circuits, while in service, this implies that adequate switching devices must be provided, and the paper considers in detail the matter of such devices.

In a paper entitled "The Use of Ground Shields in Transformers," Mr. J. S. Peck criticises the use of such shields. His conclusions are that since the ground shield does not offer absolute protection, while it increases the cost and reduces the efficiency of the transformer and introduces mechanical and electrical difficulties, its use for high-pressure transformers is a theoretical rather than a practical means of protection. He considers that the grounding of the low-pressure winding at the neutral is a safer, more practical and cheaper method of protection than is the use of the ground shield.

Mr. H. C. Wirt will have for the subject of a paper, "The Protection of High-Pressure Transmission Lines from Static Discharges," which will be considered under the heads of ground wires and reactive coils. Mr. Wirt expresses the opinion that a transmission line can be protected from lightning discharges by suitable apparatus placed in the stations, and that it is not necessary to use ground wires, though possibly an exception should be made in cases where poles are shattered with great frequency. As to the use of reactance coils, he considers there can be no question that such coils are effective and, therefore, should always be used.

A Government Wireless Mix-up.

According to the New York *Evening Post*, the proposed government operation of coast line wireless stations has led to considerable friction between the Navy, Army, Treasury and Agricultural Departments, with the Department of Commerce and Labor yet to be heard from, and Congress, at its next session, will be called upon to deal with the imbroglio.

According to the *Post* correspondent, the Navy Department desires to abolish all shore line stations in competition with the Slaby-Arco system, and to make that exclusive within zones of 240 miles, though it is stated that this system has proved effective only over a radius of 70 miles. Meanwhile, the ocean-going steamers have installed the Marconi instruments, and that company refuses to exchange with the Slaby-Arco system, or any modification of it.

Gen. Greely regards the navy scheme as impracticable, and says that while all but one company may be driven from the coasts of the United States, continental and insular, so long as steamship companies prefer and employ another system, there is no redress, and the adoption of one scheme to the exclusion of all others is a detriment to the country, unless by means of it ships may be reached. Moreover, beyond a three-mile limit lie the high seas, where no one country can hope successfully to control.

The several departments are using various wireless systems, each under bonds protecting the United States from possible complications from patent infringements. The army is experimenting with a combination of the De Forest and the Signal Corps, or Wildman system, having purchased apparatus in the open market whenever it was considered by the Signal Corps reasonable in price. The extreme test of its efficiency is to be made in Alaska, where it is hoped to cover 107 miles. This is across a bay where ice for three successive winters has swept away the cable. The department has been driven to use a wireless system or go without communication. The army claims that its system is the best for practical purposes, and that having experimented in this line long before the navy began, it ought to have the weight of authority.

In the customs collection district of Puget Sound the Treasury Department is employing what is termed by both the army and navy experts a nondescript service, which these experts say is of use for a distance of only twelve miles. The Agricultural Department is in a tangle with Fessenden and claims to own the system which bears his name, because he developed it while he was employed by the department.

Hudson River Power in the General Electric Works.

TRANSMITTED water power from Spier Falls on the Hudson River is used in the General Electric Works more than 30 miles away. Electric power from the Hudson has operated parts of the machinery at Schenectady since 1898, the first supply having been from the water power plant at Mechanicville, some 15 miles distant. Within the past year, however, the great station at Spier Falls has been started, new transmission lines have been strung and now both of these water powers are delivering energy for use in the greatest electric manufacturing plant in the world. As the generating equipment at the Spier Falls plant is still incomplete, the maximum amount of power covered by the contract between the Hudson River Water Power Company and the General Electric Company is not yet delivered at the works of the latter company. This contract is said to call for a maximum delivery of 10,000 hp under certain conditions, and the General Electric Works have already received as much as 6,000 kw.

Between Spier Falls and the General Electric Works there are two three-phase, 40-cycle, 30,000-volt circuits. Both of these circuits are composed of medium hard bare copper wires, the size of wire in one circuit being 1/0 and in the other circuit 3/000 B. & S. gauge. At Alplaus switch house through which these lines pass at a point about five miles north of the General Electric Works, they are joined by a three-phase circuit of No. 3/0 wire from the Mechanicville water power station. By connections at this switch house energy from Spier Falls may pass to the General Electric Works over one of the two circuits, and energy from Mechanicville over the other, or both circuits may transmit the Spier Falls power.

After crossing the Mohawk River and the Erie Canal the two circuits of bare wires from Alplaus switch house enter a terminal house of special design that stands between the Erie Canal and a branch of the New York Central & Hudson River Railroad, on land of the General Electric Company. From this terminal house the two 30,000-volt circuits cross River Road, Schenectady, by means of six insulated cables, and enter the tower on a transformer house that stands in the yard of the electric works. In this house are located transformers that lower the pressure of the transmitted energy to 10,000 volts, and from these transformers the secondary circuits pass at once to the switchboard in what is known as power station No. 13, which is nearby.

At this switchboard the 10,000-volt current is distributed through transformers to four rotary converters, to a motor-generator, to a shop-testing circuit, and through several cables to the new Dock Street sub-station of the Schenectady Railway Company. From this sub-station both the railway system of this company extending to Albany and Troy, and also the local system of light and power in Schenectady are supplied with current, as described in the ELECTRICAL WORLD AND ENGINEER of May 14, 1904. The lines to the sub-stations at Colone and Latham's Corner on the Schenectady railway system formerly ran back to the switchboard at the General Electric Works, but these lines now enter the Dock Street sub-station.

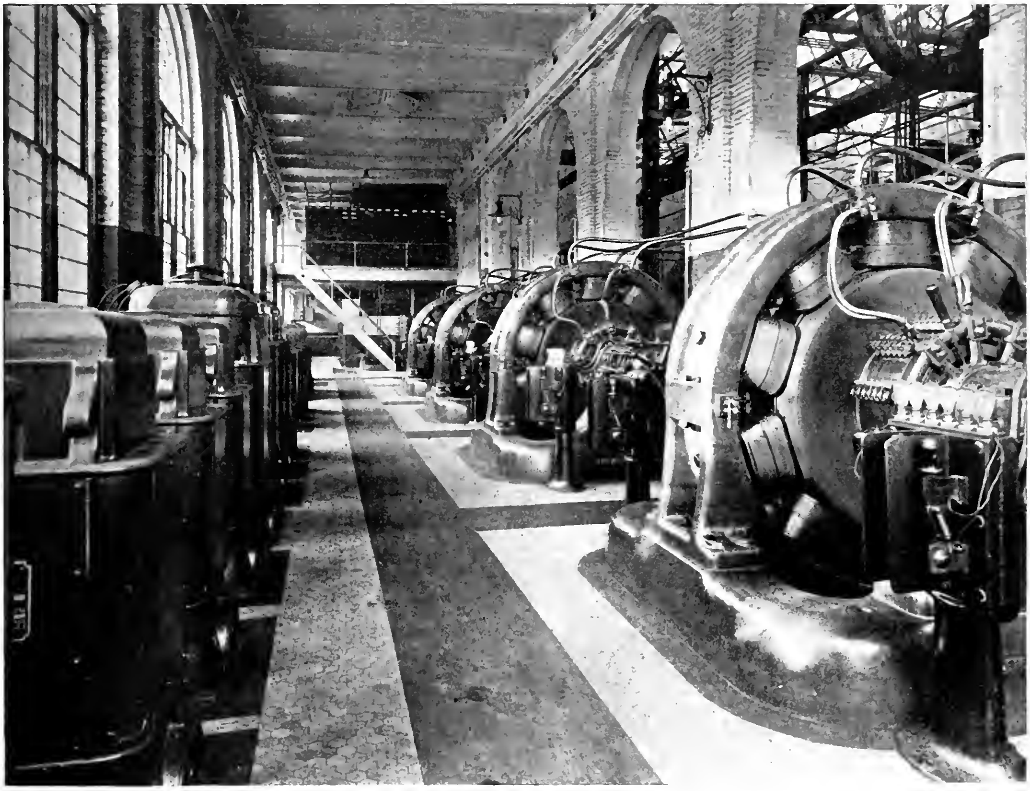

FIG. 1.—POWER STATION AT GENERAL ELECTRIC WORKS, WHERE CURRENT FROM SPIER FALLS IS CONVERTED.

The terminal house of the Hudson River Water Power Company on the General Electric property, where the bare 30,000-volt circuits from Spier Falls and Mechanicville enter, is a two-story building with brick outside walls resting on a concrete foundation. A layer of concrete 6 in. thick forms the ground floor of this house, its second floor is concrete supported by steel beams, and the roof is composed of 2¾-in. hemlock planks covered with tar and gravel. In outside dimensions at its first floor level the building measures 6 by 30 ft., and the center of the roof is 23 ft. 6 in. above the ground floor. From the ground floor to the ceiling of the second floor the distance is 10 ft. For the height of the first story the outside brick walls are 12 in. thick, and for the second story their thickness is 8 in. An 8-in. brick wall running parallel with the longer sides of the terminal house divides its first story into two parts, one of which is 5 ft., and the other 4 ft. 4 in. wide. At each end of the house there is a door to each of the apartments thus formed.

The second floor of the house forms a single room and this is entered by a door at each end that opens onto an iron platform,

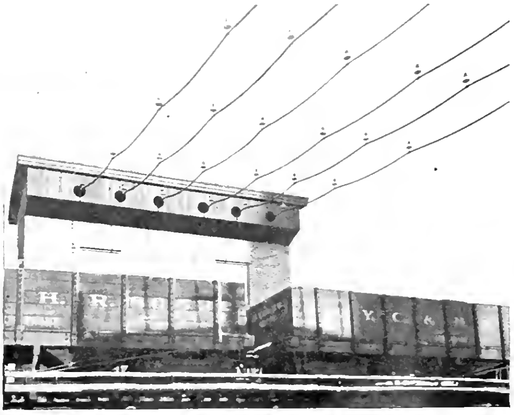

FIG. 2.—30,000-VOLT LINES OVER RIVER ROAD AT GENERAL ELECTRIC WORKS.

from which an iron ladder leads to the ground. Besides small windows in the doors, each floor is lighted through two windows in the River Road side. The upper story of this terminal house contains knife switches on one side, and oil switches on the other side for the circuits that enter it.

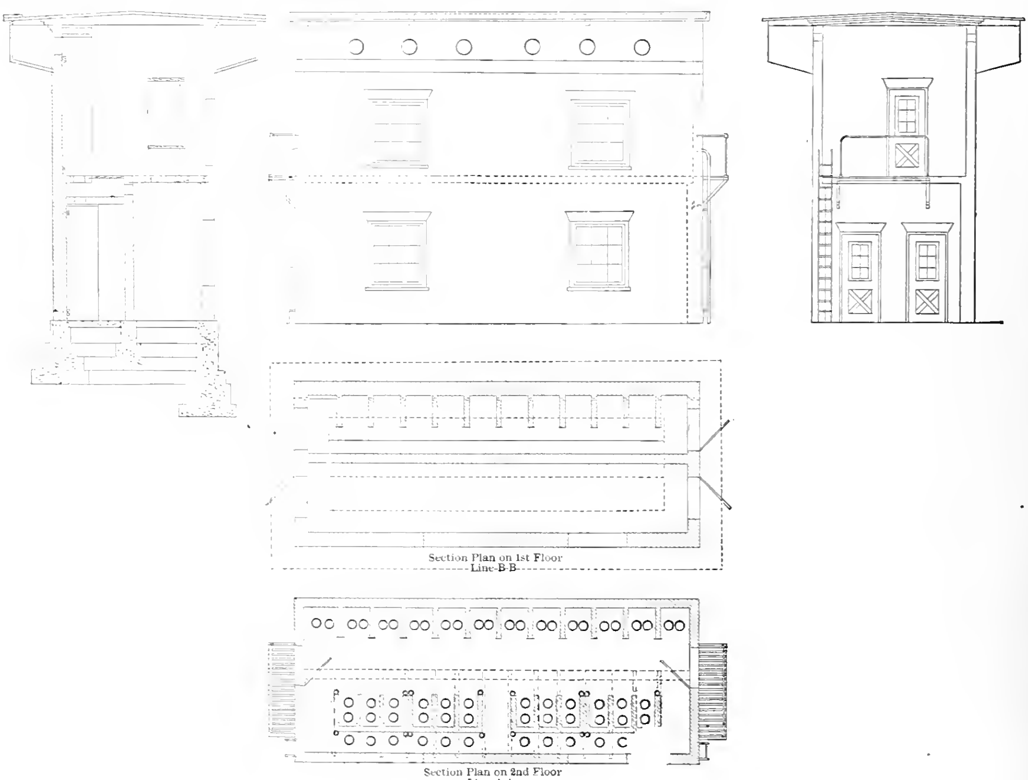

Fig. 3.—Elevations and Plans of Terminal House at Schenectady.

In the apartment on one side of the first floor there are the lightning arrester cells, and in the apartment on the other side there are instrument transformers and recording wattmeters. Along each of its longer sides the roof extends beyond the wall of the terminal house, and from the roof a weather shield made of boards drops down and turns in toward the wall, so that its lower edge is distant 3 in. from the wall and 19 ft. 1½ in. from the level of the ground floor. In the long side of each wooden wind shield there are six circular openings of 15 in. diameter each, and the brick wall next to each wind shield contains six circular openings of the same diameter and directly in line with the corresponding holes in the shield. The centers of all of these circular openings are 19 ft. 10½ in. above the level of the first floor.

On the canal side of the terminal house the six bare wires of the two, three-phase circuits from Spier Falls enter through the six circular openings on that side to the second story. On the River Road side of the house the six insulated cables representing these circuits leave through the six openings there, and cross the road to the tower of the transformer building. Directly in front of each 15-in. circular opening in the brick walls of the terminal house, and with its axis distant about 10½ in. from the inside surface of the wall there is a porcelain insulator mounted on an iron rod that passes entirely through it. The length of this insulator is about 14 in., and the diameter of each of its four petticoats is 9 in. At a point midway of the length of each insulator and with two petticoats above, and two below, the conductor is secured that passes through the adjacent opening.

Each of the six conductors that enter the terminal house from Spier Falls passes directly to a three-point, double-blade knife switch after leaving the insulator just mentioned. One blade of this knife switch connects the incoming conductor with a bank of lightning arresters in the first story, and the other blade of this switch connects with one pole of an oil switch on the second floor. The circuit of the conductor just mentioned, after passing through the oil switch, enters a single-blade knife switch where a tap is taken from an instrument transformer, and then rises to an insulator in front of one of the circular openings on the side of the terminal house next to the River Road. Near the insulator last mentioned a rubber-cov-

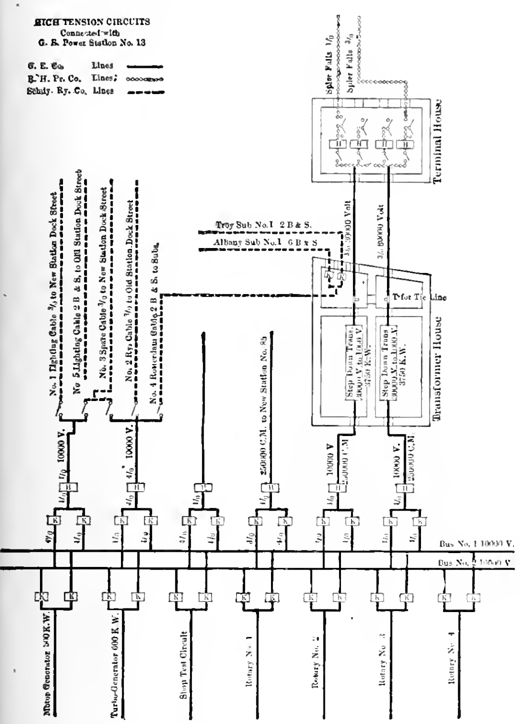

FIG. 4.—DIAGRAM OF HIGH-TENSION CIRCUITS.

ered cable is connected to the conductor in question, and this cable passes out through the 15-in. opening and across the River Road to the tower on the transformer house. Each of the six insulated cables in. deep from back to front, and 24¾ in. wide, except as to the end cells. The walls between these cells and also their roofs are 4 in. thick. Each of these cells is intended to contain one of the double-blade knife switches already mentioned, but at present only six of the cells are occupied because only two three-phase circuits now enter the terminal house from Spier Falls. The terminals of each double-blade lever switch are mounted in large iron caps carried on porcelain insulators, and these insulators are supported by large wooden pins that enter a wooden frame in each cell.

On the first floor of the terminal house and directly beneath the twelve cells just described on the second floor, there are twelve other cells like those above. These cells on the first floor are intended to receive the banks of lightning arresters for the several conductors of the entering transmission circuits, and six of the cells are now so occupied. In each of these six cells there is a wooden frame on which are mounted 42 of the brass cylinder type of lightning arresters. Each arrester carries five small brass cylinders on a porcelain base, and between the sides of these cylinders there are four air-gaps each about 1/32 in. in length. The group of 42 arresters

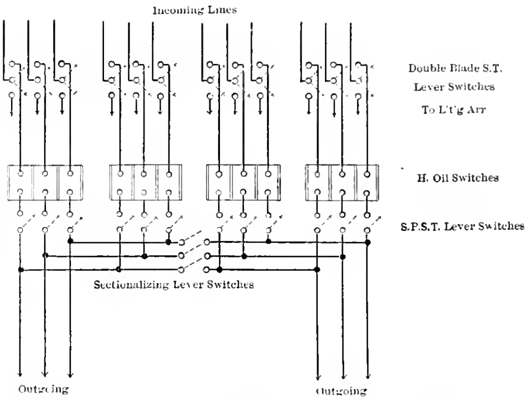

FIG. 6.—DIAGRAM OF MAIN CONNECTIONS, SCHENECTADY SWITCH HOUSE.

joined in series connects one conductor of a circuit with the ground, so that any discharge over the arresters must jump 168 of the 1/32-in. air-gaps.

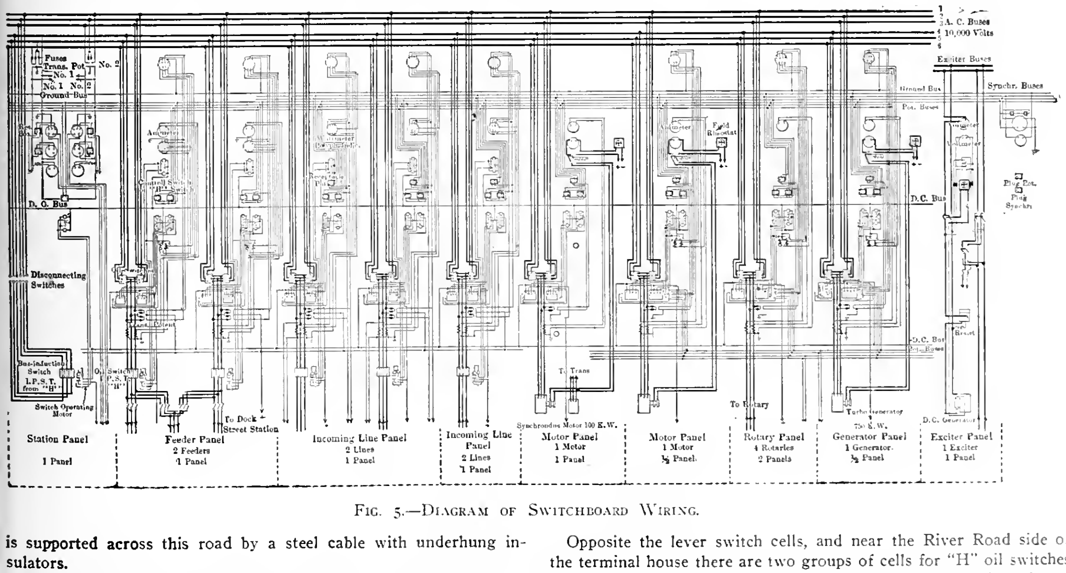

FIG. 5.—DIAGRAM OF SWITCHBOARD WIRING.

is supported across this road by a steel cable with underhung insulators.

Each of the twelve circular holes, that pierce the outer brick wall of the terminal house for the circuits from Spier Falls to enter, opens into a brick cell on the second floor that is 10 ft. 9 in. high, 27

Opposite the lever switch cells, and near the River Road side of the terminal house there are two groups of cells for "H" oil switches of General Electric make. Each group consists of six cells and provides for two three-pole switches of the type just named. The six cells for two switches occupy a space 10 ft. 9 in. long, 2 ft. 9 in. wide and 7 ft. 4¾ in. high above the floor. The back and end walls of these cells are of brick 4 in. thick; the side walls between different poles of the same switch are also 4 in. thick, and the soapstone tops and inside shelves have a thickness of 2 in. each. From front to back each cell is 29 in. deep, its width is 16 or 17 in., and its height from interior shelf to top is 5 ft. ¾ in. The three adjacent cells at each end of each group are designed to contain the three sets of double-break contact parts that go to make up a triple-pole, 200-amp., 30,000-volt oil switch, form H, there being one pole in each cell. On the soapstone tops of the cells there is mounted the electrically-operated mechanism of the switches.

As only two circuits now enter the terminal house from Spier Falls, only two of these 200-amp., 30,000-volt switches have been installed. When the two other circuits from water power plants for which provision has been made enter the terminal house and connect with switches like those just named, two of the four entering circuits will connect through lever switches with each of the two circuits that pass from the terminal house to the tower of the transformer house. At the present time each of the two circuits from Spier Falls connects through its oil and lever switches with one of the two circuits that go to the transformer house, but these last-named circuits may be put into multiple by means of lever switches. These electrically-operated, 200-amp., 30,000-volt oil switches in the terminal house are controlled at the switchboard in power station No. 13 of the General Electric Company.

The six conductors of the two three-phase circuits from the terminal house enter the tower of the transformer house through six circular openings in the brick wall, each of which is 15 in. in diameter, and the three openings for each circuit are spaced with their centers 4 ft. apart. An interior brick wall divides this tower into two compartments, and the wires of each circuit enter one compartment. Within these compartments each conductor of the two circuits has a T for a tie line connection, and openings through the wall that separates the two compartments permit three jumpers or tie lines to pass between the two circuits and thus put them in multiple, when desired. From its tower compartment each circuit passes into a separate transformer room, and the two tower and two transformer rooms take up the entire transformer building.

This building was not especially constructed for its present purpose, but it has been remodeled to fit it for a transformer house. Except as to its tower at one end this building is one story in height, and its four sides have lengths of 29 ft. 5 in., 48 ft. 11 in., 30 ft. and 42 ft. 11 in. on the outside, respectively. The external walls of this transformer house are of brick, and are 12 to 16 in. thick; a 12-in. internal brick wall separates the tower from the one-story part, and a 16-in. wall divides the one-story portion into two nearly equal rooms. In both rooms there are wooden floors laid over 6-in. beds of concrete, and the roof is laid with slag on 1¾-in. plank. In that part of the roof over each room there are two 30-in. circular ventilators of sheet iron.

Beneath each of the two transformer rooms there is a compressed-air pit 33 ft. long, 7 ft. deep, 3 ft. 4 in. wide in the one case and 4 ft. 2 in. wide in the other. Three transformers and a motor-driven blower are located over one of these pits, and four transformers and a like blower over the other pit. Three of these transformers are regularly connected to one of the transmission circuits and three others to the other circuit, and the seventh transformer is a spare. Each of these air-blast transformers is rated at 1,200 kw, 40 cycles and 15,030 to 9,700 volts. The three-phase transmission circuits that leave the step-up transformers at Spier Falls with a voltage of 30,000 have about 26,500 volts between each two conductors in the transformer house just described. Each group of the 1,200-kw transformers have their three primary coils connected to one of the 26,500-volt circuits in the Y form, and three secondary coils are connected in the Δ form, so that the transformation is from 26,500 to 9,700 volts, or thereabouts. The nominal rating of these six main step-down transformers is thus 7,200 kw, and on them depends the supply of transmitted water power for a large amount of machinery at the General Electric Works, the entire load of lamps and stationary motors on the electrical supply system at Schenectady, and the railway lines of that city with the branches to Albany and Troy.

From the secondary coils of each of the two banks of transformers just considered, an underground cable carrying three conductors of 250,000 cm. cross-section each passes to a 10,000-volt, 500-amp., three-pole, oil switch in power station No. 13. Two circuits connect this H switch with two sets of 10,000-volt, three-phase bus-bars, each circuit passing through a 10,000-volt, 300-amp., three-pole, K oil switch on the way. By the arrangement of switches in the terminal house either transmission line from Spier Falls may be connected to either set of the 10,000-volt bus-bars in the power station through either bank of transformers in the transformer house, or both transmission lines and both banks of transformers may be joined in multiple. These two sets of 10,000-volt, three-phase bus-bars distribute current to a shop-testing circuit, to the Dock Street sub-station, and to a motor-generator and from rotary converters in the old power station. The shop-testing circuit is supplied through a 250-kw, 40-cycle transformer that reduces the pressure from 10,000 to 120 volts. This transformer may be connected to either set of bus-bars through one of two K oil switches. Current to the motor-generator goes from either set of bus-bars through a K oil switch. The motor of this generating set is rated at 600 kw, 10,000 volts and 40 cycles, and is direct-connected to a 500-volt, direct-current generator of equal capacity, which operates at 480 r.p.m.

A bank of three transformers for each of the four rotary converters can be connected to either of the two sets of 10,000-volt bus-bars through one of two 300-amp. K oil switches that are provided for the purpose. Each of these four banks of transformers reduces the 10,000-volt alternating pressure so that each rotary converter delivers direct current of 250 volts at its commutators. The indi-

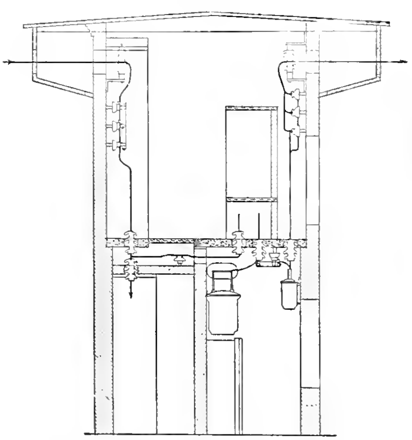

FIG. 7.—ELEVATION OF APPARATUS IN SCHENECTADY SWITCH HOUSE.

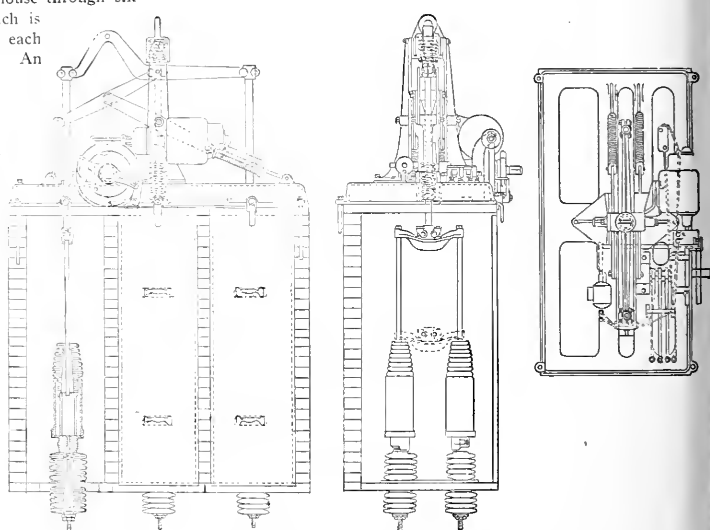

FIG. 8.—SECTIONS AND PLAN OF OIL SWITCH IN SCHENECTADY TERMINAL HOUSE.

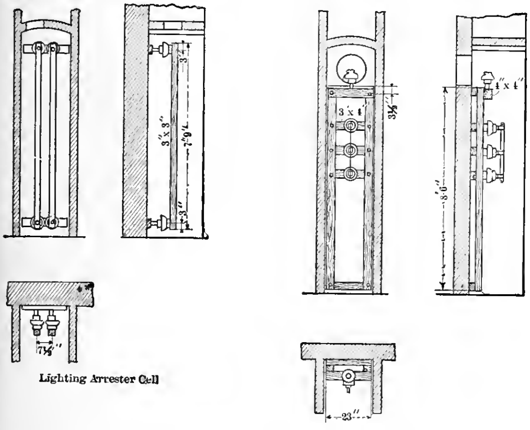
vidual rating of these four rotary converters is 600 kw; they operate at 480 r.p.m., and the armature of each is double-wound and has two commutators. By connecting the two commutators of any converter in series, a voltage of 500 is obtained when desired. Current from these, from rotary converters and also from the 600-kw, 500-volt generator driven by the 10,000-volt motor is distributed to 250-volt and 500-volt motors in various parts of the General Electric works.

Two groups of switches are employed to connect the two sets of 10,000-volt bus-bars with underground cables that run to the Dock Street sub-station. Each of these groups consists of two three-pole, 300-amp. K oil switches that join respectively the two sets of bus-bars with a type H oil switch. Lever switches connect each H oil switch with one or two underground cables for the Dock Street sub-station. There are three of these cables each containing three 3-0 stranded copper conductors. One cable is devoted to the railway apparatus, and another to the lighting apparatus in the Dock Street sub-station, and each of these cables joins one of the type H oil switches at the power station through a lever switch. The third of these underground cables may be connected through either of two lever switches with the form H oil switch that carries the lighting cable, or the corresponding switch that carries the railway cable, as desired.

The cable from the power station that formerly ran to the Albany



Lever Switch Cell

FIG. 9.—CELL EQUIPMENTS, SCHENECTADY SWITCH HOUSE.

and Troy sub-stations of the railway has been discontinued, and these sub-stations now take current from that at Dock Street. At the Dock Street sub-station the total capacity of rotary converters is 1,800 kw, of motor-generators 1,550 kw, and of both 3,350 kw. In No. 13 power station at the General Electric works the combined rating of the motor-generator, the four rotary converters and the transformer for the testing circuit amounts to 3,250 kw, so that the capacity of the apparatus connected to the transmission system at this station and at that on Dock Street is 6,600 kw, as a total. To this must be added the rotary converters at the Albany and Troy sub-stations of the Schenectady railway system.

Current for all the foregoing apparatus flows through the two sets of 10,000-volt, three-phase bus-bars in No. 13 power plant, and is normally delivered by the transmission lines from Spier Falls through the six transformers of 7,200-kw capacity that reduce the pressure from 26,500 to 9,700 volts. If the supply of energy from Spier Falls fails, the bus-bars just named may be connected to a single 600-kw, 10,000-volt, 40-cycle, three-phase turbine generator at the General Electric works, or either or all of four 1,500-kw, 10,000-volt, 40-cycle, three-phase turbine generators now located there in new power station No. 85. This power station is designed to contain six of these 1,500-kw turbines, and they will all take steam at 160 pounds pressure and operate at 800 r.p.m.

The facts as to this delivery of transmitted water power to the General Electric works, probably the largest delivery of its kind to a manufacturing plant anywhere in the world, have been secured through the kindness of Mr. A. L. Rohrer, of the General Electric Company.

New Engineering Building at the University of Colorado.

The University of Colorado, located at Boulder, thirty miles northeast of Denver, has recently completed a noteworthy addition to its engineering equipment in the form of an extension of the main building devoted to applied science. The old building has been supplied with new equipment, so that the whole structure now represents in every respect a thoroughly modern piece of educational machinery.

The engineering building is a two-story brick structure, 175 ft. long by 85 ft. wide, and is situated at the eastern end of the quadrangle, close to the track of the Colorado & Southern Railway. The entire first floor of the original structure is devoted to the shops, power plant and electrical laboratories, while the hydraulic, cement and mechanical laboratories are located in the basement.

On the first floor are located the office of Prof. Dates, dean of the engineering school, a department reading room for electrical students, recitation, drafting and photometer rooms, an electrical measurement laboratory, dynamo room, machine shop, forge shop and boiler room. The engineering building, in common with all other buildings on the campus, is lighted by electricity and heated from the central boiler plant. The second floor of the entire building, with the exception of the wood-working shop, which is just above the machine shop, is occupied by class rooms, drawing rooms and the studies of the professors of civil and mechanical engineering, superintendent of shops, etc. The electrical recitation room on the first floor contains an instrument case holding about $3,000 worth of apparatus, and an interesting exhibit of samples of wire and cables, rail bonds, the various parts of an incandescent lamp arranged in the order of their assembling in manufacture, and a dissected dynamo which shows every part of the machine in single pieces. There is also a collection of armored conduit, fuses and high-potential insulators.

The photometer room is large and well ventilated, containing a Reichsantalt photometer with a two-meter scale, Bunsen and Lummer Brodhun screens, standards of lamps, etc. The electrical measuring laboratory is well equipped with wattmeters, synchronizers, voltmeters, ammeters, balances, lamp banks, transformers and water rheostats. In the dynamo room are located a 50-hp Ames engine and a Harrisburg engine of the same capacity, a jack shaft with pulleys and a 30-kw, 125-volt, 4-pole, compound-wound, 250-r.p.m. Westinghouse direct-current generator, a 35-kw, 110-volt Akron generator, a General Electric bipolar generator, rotary converter, induction and synchronous motors. A 10-kw Westinghouse rotary is soon to be added to the equipment. There are also water rheostats for taking up loads, lamp banks and switchboards.

The civil engineering laboratory is well equipped with surveying instruments of the various standard makers, transits with solar attachments, mining transits, levels, compasses, plane tables, a sextant, barometers and a good collection of drawings and models used in design work. The cement laboratory is equipped with a 200-pound Fairbanks shot machine, a 100,000-pound Olsen testing machine, molds and tanks. About 1,600 sq. ft. are occupied by the hydraulic laboratory. The equipment consists of a tank in the third story of the building, affording a constant head, and in the laboratory, tanks supplied with various shaped notches and orifices for discharge measurements, channels of various shapes, benturi meters and other pieces of hydraulic apparatus.

The mechanical laboratory uses the testing machine above mentioned, and is equipped with a great variety of oil testing apparatus, calorimeters, injectors, meters, burettes, thermometers, pyrometers, micrometers, steam gauges, anemometers and indicators. The University power plant contains three boilers of 200-hp capacity, pumps, traps, etc., so that tests of fuse economy are arranged with great ease.

While there is ample room in the new building for the installation of much more apparatus, it is gratifying to note that nearly all the equipment thus far purchased is of excellent quality, and of sufficient variety to enable a wide range of experimental work to be carried on. One does not expect to find such complete equipment in the Rocky Mountain States as is here in evidence. All the machinery in the building is driven by electric motors. The foundry contains a Newton cupola furnace, capable of melting two tons of iron per hour, and the forges and cupola are served by three centrifugal fans, operated by a 10-hp motor.

Experiments With the Magnetic Detector.

In the May number of the *Physical Review*, Prof. Arthur L. Foley gives the results of some experiments on the magnetic detector of electric waves which formed the subject of a Royal Society communication made in 1902 by Marconi, which has also been known as the Rutherford detector. The instrument as used and described by Marconi, consisted of a "core or rod of thin iron wires on which were wound one or two layers of thin insulated copper wire. Over this winding insulating material was placed, and over this again another longer winding of thin copper wire contained in a narrow bobbin." One terminal of the inside winding was connected to earth, the other to an elevated conductor. The ends of the outside winding were connected to a telephone. A horseshoe magnet, suitably placed, was moved by clockwork so as to cause a continuous change or successive reversals, of the magnetism of the iron core. Electric oscillations appeared to reduce the effects of magnetic hysteresis, hence the magnetism of the iron core increased or decreased suddenly with each spark of the transmitter, inducing a current in the outer winding connected to the telephone.

Marconi noticed that "the signals in the telephone are weakest when the poles of the rotating magnet have just passed the core and are increasing their distance from it, whilst they are strongest when the magnet poles are approaching the core." To obtain more definite results, Prof. Foley arranged to use a ballistic galvanometer instead of a telephone, and to take readings for various determined positions of the magnet and core.

The core, which was 5 cm. long, consisted of twenty-six pieces of annealed piano wire, .063 cm. in diameter. Over this was wound a single layer of 200 turns of No. 36 silk-insulated copper wire. One end of the coil was connected to a vertical wire 200 cm. long, the other end was put to earth. The terminals of the outer or secondary coil of 1,000 turns of No. 30 copper wire were connected to a Rowland D'Arsonval galvanometer through a key arranged to short-circuit the galvanometer after each throw of the needle. This brought the needle to rest very quickly, and permitted the position of the magnet to be changed without affecting the galvanometer.

The induction coil (one inch) of the transmitter was adjusted to give a 2-mm. spark between two small brass spheres, one connected to a vertical wire 200 cm. long, the other to earth. The distance between the transmitter and receiver was varied from two meters to twenty meters. No effort was made to "tune" the circuits. The primary and secondary coils were fastened in place on a board

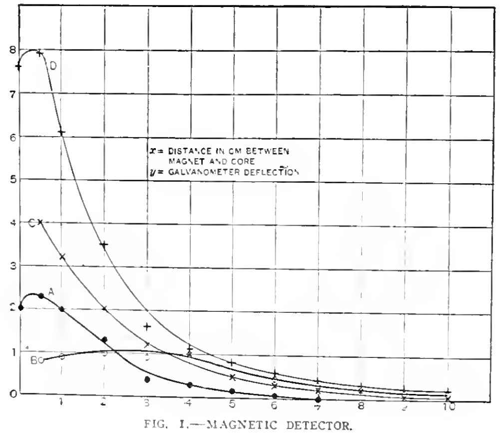


FIG. 1.—MAGNETIC DETECTOR.

grooved and graduated so that a horseshoe magnet could be slid back and forth in the same horizontal plane with, and in a direction at right angles to, the iron core, and placed at any desired distance from it. To get a reading the galvenometer was first short-circuited and the magnet placed in position. The short-circuit was then broken, the transmitter operated as long as the deflection of the needle was increasing, and the throw observed.

The curves in Fig. 1 give the throws of the galvanometer for the given distances between the magnet and core as follows:

A. When the magnet is placed 10 cm. from the core and moved one space nearer each successive reading. *B*. When the magnet is placed in contact with the core and is moved one space farther from it each reading. *C*. When the magnet is removed and the transmitter operated between readings. *D*. When the magnet is turned over (the field reversed) between readings.

A comparison of curves *A* and *B* shows that the sensitiveness of the magnetic detector depends upon both the distance and direction of motion of the moving magnet. When the magnet is near the core the detector is more sensitive when the magnet is approaching,

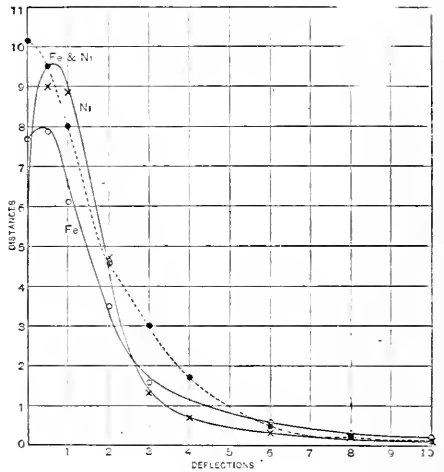

FIG. 2.—MAGNETIC DETECTOR.

but when some distance from the core the detector is more sensitive when the magnet is receding. Both curves indicate a maximum of sensitiveness at a distance from the core, the distance being less when the magnet is approaching. Since nickel is more susceptible than iron in weak magnetic fields, and less susceptible in strong fields, Prof. Foley concluded that a more uniform sensibility for varying distances between the moving magnet and core might be obtained by making the core of nickel.

Four cores were made, each one being 5 cm. long, approximately .4 cm. in diameter and being wound with 200 turns of No. 36 copper wire. Core 1 consisted of 26 pieces of piano wire .063 cm. in diameter. Core 2 of 10 pieces of piano wire and 10 pieces of nickel wire, .082 cm. in diameter. Core 3 of 2 pieces of piano wire and 13 pieces of nickel wire. Core 4 of 14 pieces of nickel wire. The curves of Fig. 2 give the deflections at various distances between the magnet and each of the four cores, the magnet being moved one space at a time and having its poles reversed after each reading.

The sensitiveness of the detector with a nickel core was not very different from the sensitiveness when an iron core was used. Contrary to expectations, however, the sensitiveness with the nickel core appeared to be the greater in strong fields and with the iron core in weak fields. Both showed a maximum of sensitiveness at a short distance from the magnet, the maximum for nickel being the farther removed. The nickel core proved to be more sensitive than the iron core for distances up to 2.5 cm.

When the detector was worked with the mixed core of iron and nickel wires the deflections of the galvanometer increased as the magnet approached the core, even up to the point of contact. The curve (*Fe* and *Ni*, Fig. 2) lies above the *Fe* curve at all points and above the *Ni* curve at most points, showing that a mixed core consisting of annealed piano wire and hard drawn nickel wire, produced a more sensitive detector than was obtained by using a core of piano wire only. The detector gave small deflections of the galvanometer when I used an antimony core; also when a core of iron filings was used contained in a thin walled glass tube. A core of bismuth gave no deflection.

The form of the curves of Figs. 1 and 2 probably depends upon other points than those here considered, as for instance the frequency and intensity of the oscillations of the transmitter, and the annealing of the steel wires used in the core.

Some Telephone Problems in Farming Communities.

By HOWARD S. KNOWLTON.

THE growth of the telephone industry in the United States presents a remarkable evolution of apparatus and methods. It would be difficult to express in a single paragraph the revolutions which the technical side of the art has passed through in its advance from the crude mechanism of the early days to the highly-developed and organized appliances of the present. Although the common-battery, lamp signal, multiple switchboard is one of the latest additions to standard practice, involving many operating and maintenance problems unfamiliar in the first part of the closing decade of the nineteenth century, it is a logical and scientific outcome of all that came before it, and a notable illustration of the pursuit of economy in the modern industrial fabric. There is scarcely a piece of telephone apparatus in existence to-day which may not be improved in some detail but a single year hence, although its fundamental principle may be utilized long after this page has yellowed with age. Even the familiar Bell receiver has been tremendously increased in power by doubling the magnet poles and employing a closed magnetic circuit. Permanence is yet to be printed in the dictionary of telephony.

Urban communities reaped the benefit of the invention of the telephone long before the agricultural districts could avail themselves of it. The experience of the electric railway is a close parallel. For almost twenty years after the electrical transmission of speech was an accomplished fact the farmer had little conception of its possibilities when installed in his home, and still less expectation of being offered a rate within his means. Step by step, however, the telephone system reached out beyond the city, until to-day the market has been brought to the farmer's very door by its agency, and the exploitation of the rural district is increasing by leaps and bounds.

With the extension of the telephone into the country regions has come a serious problem. The cost of construction per subscriber served is unavoidably high, in view of the low density of population, long lines to be built, remoteness of railway or river transportation facilities and expense of maintaining the construction force away from home. The physical obstacles offered by huge mountain ranges and other rough country may easily rise to alarming proportions. Maintenance likewise is a heavy expense, after the lines are placed in operation over extended territory. The adoption of a rate which shall be fair to both company and farmer is, therefore, a question of the first magnitude in importance. Telephone companies the country over are face to face with this pressing problem.

The manner in which the question has been met in the West by one of the most progressive Bell companies in that part of the country is full of suggestion. The writer takes a leaf from the record of the Colorado Telephone Company as the concrete example.

For some time past there has been a feeling among the ranchmen of Colorado that lower telephone rates would be much appreciated. Party line ranch service at a distance of two and one-half miles radially from the local exchange centers has been charged at the rate of $30 per subscriber's station per year, with the exception of ranches located near larger centers of population like Denver, Colorado Springs, Pueblo, etc. This rate, $30, did not increase as the distance from the central office became greater. In the vicinity of Ouray and Silverton higher rates were necessary, in view of the extraordinary wildness and roughness of the mountains in this portion of the State. The region around these two places is called the San Juan country, and while it is famous for stupendous scenery it is no easy place to maintain telephone lines.

The Colorado company, therefore, made a careful study of ranch service, with a view toward meeting the situation. An example of the thoroughness with which this work was done is evidenced by an exhaustive study which the engineering department made in January of the cost of service on the group of lines extending northeast of the town of Longmont, supplying ranches in the region adjacent to Highland Lake. This inquiry involved a careful inventory of every pole, insulator, cross arm, wire, guy and telephone instrument on a lead about 50 miles long; a traffic record extending over a period of one month, in which every originating call on this lead was counted, day and night; and a close examination of all receipts and expenses in connection with the Longmont exchange which had a bearing upon this group of lines.

After the ranch problem had been thoroughly gone over by the officials of the company, conferences were held with prominent ranchmen, and the question of rates gone into afresh. The upshot of the matter was the issuing of a circular letter by the president of the Colorado Telephone Company, Mr. E. B. Field, a copy of which was sent to every ranch subscriber in the State.

Mr. Field entitled his circular "Facts, not Promoter's Promises, Regarding Ranch Telephone Service," and succeeded in making therein a remarkably plain statement of the telephone company's attitude and propositions in regard to the whole matter. Certain portions of this circular are of so much interest to managers of electric properties that I have no hesitation in quoting them, wholly or in part:

"The Colorado Telephone Company wants to furnish the ranchmen of the State with telephone service. The ranchmen in the State want to be furnished with telephone service by someone. It is to be regretted that there has grown up, not only in Colorado, but in the entire United States, a very unfortunate misunderstanding upon both the part of the telephone companies and the farmers as to the attitude of each other on this question. When two intelligent persons, or bodies of men, have a wrong opinion of each other, it usually turns out that neither understands the real position of the other, and it is to try in a business-like manner to clearly and fairly state the facts on both sides that this paper is written."

Mr. Field then made the point that as most people know their own business best, it is safe to say that the employees of the telephone company do not have a skilled knowledge of ranching, and that the ranchmen, on the other hand, are not experts in the telephone business. It is fair to presume that each class of men understand their own business, or they would not long remain in it. A ranchman may have run a telephone line from his barn to his house and bought two telephone instruments, but for this reason he does not necessarily know any more about the question of telephone service than the telephone man knows about farming, because he has raised a few potatoes in his garden.

One of the misunderstandings that has arisen is the farmer's idea that telephone companies are grinding monopolies, intent on fleecing the farmers by extortionate rates to the extent of their ability to do so. "There are people all over the United States who want to sell telephone apparatus, who are constantly catering to and fostering this feeling on the part of the farmers. There is also in every section some sharp, shrewd local man, who will go in with the fellow who wants to sell his telephones and supplies, and advise his fellow towsmen to go into the scheme and then receive a commission himself on the sales, or an interest in any scheme carried out." Mr. Field then quoted an example from the advertising matter which is constantly being sent to the farmers by manufacturers, which advised the farmer "not to be fooled with the sugar-coated pill that telephone companies offer," saying that if the farmer will look closely he "will see the grinning skeleton behind the pill and not be fooled by the blood-thirsty monopoly." The pamphlet quoted then goes on to sing a wonderful song about how much better it will be for the farmer and the entire universe if he will only buy the apparatus of this particular company, and how much better it will be for the farmer if he has no dealings with the local company in his immediate neighborhood. It is astonishing that any intelligent farmer can be caught by such arguments, but "that a certain portion of the farming community do listen to continued assertions like the above is unfortunately true."

"On the other hand, the telephone companies, when met by this spirit on the part of the farmer have also come to the conclusion upon their part that the farmer does not want to pay a reasonable telephone rate for their service, but that they are insistent upon getting something for nothing, and it has been an unfortunate misunderstanding all around." The circular letter then states that the telephone company does not believe that the Colorado ranchman wants something for nothing, neither is he willing to give something for nothing; that the company wants to give the farmers fair rates, and that it has a better, fairer and in the end a cheaper proposition to make than any outsider can offer.

"The price at which anyone can afford to sell a thing is based upon what it costs to raise or produce it. The farmer bases the price of his live stock upon his crops, upon the labor and investment involved up to the day when he offers the stock in market. In the case of alfalfa or sugar beets, for instance, he knows what his product costs him; he knows what it costs to bring water upon the land, the cost of his fences, farm houses, implements, etc.; he must reckon the price of seed, the cost of sowing, weeding, cultivating and haresting; and then he considers the cost of hauling to market. If the crop does not give him a fair profit (and the most profit that the Colorado Telephone Company hopes to make on its business in a year is 6 per cent.) he drops that crop for something better. To the buyer who comes to the ranch and offers to take his alfalfa as it stands stacked in the field, he will sell for less than to the merchant in town who expects him to deliver it to his store, baled and ready for shipment. Were a beet sugar factory to agree to weed, cultivate and come and get his beets, relieving the farmer of all that risk and care, he would sell them for less than he would to a factory that did not do so. The same principles exist in connection with telephone companies.

"What is ranch telephone service? It is not having a telephone, for you can buy one outright for $10 or $15. Telephone service involves a telephone instrument and its care; it means also the digging of holes, buying of poles of suitable timber which will stand up under heavy storms; of first-class insulators, high-grade wire, etc. Then it involves the expense of sending out at any hour of the day, with the cost of livery, a man to repair breaks and set poles, and many times it costs the company $10 to repair a simple trouble on your circuit. You must bear in mind that the best telephone line depreciates and rots continually, and must be entirely replaced at least once in every seven to ten years, so that out of every $100 that we put into line, 10 per cent., or $10, rots away every year. Further, the telephone and the lines are not telephone service, for then comes the town investment and the investment throughout the State, and the operating labor, which enables you to communicate with hundreds of other subscribers; this means a switchboard, taxes, office rent, light and heat; it means the salaries of operators who must be on duty for you night and day, of linemen, and competent men to superintend the business to see that you are properly served."

The propositions of new rates are as follows:

1. Within one mile of the central office the company will furnish the farmer with instruments and care for the same, build all the lines, do all the work, assume entire responsibility and furnish him service inside the district in which the central office is located, at $18 per year. And beyond one mile the following rate will be charged in a small increasing amount, as the distance from the office becomes greater, all distances being measured in a "bee" line, although the distance by road is sometimes far greater: From 1 mile to 1¼ miles, $20; between 1¼ and 1½ miles, $22; between 1½ and up to a 6-mile limit, $24; between the 6 and 9-mile limits, $27; between 9 miles and 12 miles, $30; from 12 to 15 miles, $33; between 15 and 18 miles, $36, and so on. Under this plan the nearer the central office the lower the rate charged. The equity of charging an increased rental as the distance from the office increases should be apparent, because the investment in poles and wire grows greater and greater as the length of line to be built and maintained increases.

"Now, just as you will sell your alfalfa for less to the company that will buy it as it stands stacked in the field, the telephone company has various propositions to offer you if you will relieve it of some of its investment expenses and labor by furnishing part of them." It is assumed that during certain seasons of the year ranchmen have the time to perform the labor of constructing a telephone line, and it is to provide cheaper plans for telephone service, in which the company has the co-operation of the ranchman by his doing certain portions of the necessary labor, and himself owning certain portions of the plant that the following propositions are submitted:

2. This proposition gives a rate of only $12 per annum per station if one or more ranchmen will construct and take care of their line at their own expense, the company furnishing the telephones, taking care of them and giving exchange service.

3. If the farmer will not only construct his line, but also buy his own telephone and take care of it, the company will give him its switching service—exactly the same service which it gives every other subscriber—for 50 cents per month, $6 per year. The company does not ask the farmer to buy a complete telephone instrument, but will loan the subscriber a Bell receiver and transmitter, so that he will only need to buy the balance of the set, either of the telephone company for $10, or wherever else the farmer pleases. The receiver and transmitter will be loaned on a deposit of $3, which will be returned when the apparatus is given back. In case the farmers are so far from town that it would not be practicable to build to the exchange, the company will arrange to place a switchboard at some ranch, centrally located; the company furnishing the switchboard free, and the farmers furnishing the ranch operator at their own expense. The farmers would then build their lines, which would be short, and also maintain them; but the company will keep the switchboard in order, build and maintain the connecting lines from its own central office to the farmers' switchboard, the rental being $12 per annum per station.

4. This proposition provides for a switchboard in the farmer's section, furnished free by the company; maintenance and an operator to be provided by the farmers, who will build their own lines, take care of them and each pay the company $5 per year for the complete telephone instrument; or the farmers may each rent the receiver and transmitter from the company for $2 per year per set, and buy the rest of the telephone instrument; the farmers would then build and take care of the trunk line between their switchboard and the telephone office, and pay 5 cents per talk to the subscribers in the company's exchange.

These propositions cannot be called exorbitant, and are believed to cover any kind of demand which a farmer has for telephone service. The company expects a fair profit if it sells the farmer any of its commodity, and asks him to meet it in exactly the same spirit.

"One of the most seductive songs that is sung to the farmers by telephone supply sellers," Mr. Field states, "is the co-operative idea. These people ask you to form co-operative companies and want you to take a few shares each of the stock so that the farmer may share in any profits that may be made. The Colorado Telephone Company has exactly the same proposition to make to you. The only difference is that you do not have to wait for the success of a doubtful enterprise before you participate in the profits, but can, if you buy stock in our company, buy a stock that has been paying 6 per cent. dividends per annum, and is likely to do so, because our stock has paid 6 per cent. dividends for years. The price of the stock is its par value, $50 per share, and the standing of any purchaser in the company is exactly the same as that of the others who have their money invested in the business." There can be no possible reasonable antagonism between the company and the ranchman after each understands the other's position.

The Colorado Telephone Company earns upon its entire investment from 8 per cent. to 10 per cent. per annum, and reserves the difference between 6 per cent. and its 8 to 10 per cent. as a contingent fund to provide for the havoc that sleet, storms, wind, etc., play with its plant annually. It has no bonded indebtedness, and, therefore, no fixed charges to pay out for interest. This ratio of profit is made upon the existing rates. Mr. Field offers to send a copy of the annual report of the president to stockholders to any ranchman requesting it, and then states that although the business is in the nature of a monopoly, the company has the good sense to know that anything like blood-thirsty or extortionate practices would be business suicide. The argument has been made over and over again by the telephone supply promoter that the company could give lower rates if it did not have to pay such excessive royalties to the Bell Telephone Company for the use of their instruments. Since the expiration of the patents no royalties whatever have been paid. Instead, the payment is a small annual rental for the hand telephone and transmitter, which is actually less than the interest, maintenance and depreciation on the cost of hand telephones and transmitters were these to be manufactured or purchased outright. This rental is in fact an absolute saving to the Colorado company rather than a serious or extraordinary expense. "The promoter has so frequently asserted that he could build telephone lines so much cheaper than the Colorado company that an idea may have gotten into the minds of the ranchmen that we are extravagant in spending our money in telephone construction. The best telephone engineers in the world have stated that the entire plant of the company in the whole State of Colorado, irrespective of sections, could not be replaced to-day at the figure at which it stands upon the books and covering which cost of construction the capital stock has been issued. First-class lines such as this company constructs cannot be built cheaper in this State."

Mr. Field closes by asking the ranchman to choose between the statements of the Colorado Telephone Company and the promoters.

It is evident from the foregoing that the farmer has been met far more than half way by the particular company quoted. Certain it is that the days of concealment are past, if corporations expect to give to and receive fair dealing from their patrons. If the farmer can be made to see just what a company can do he will be much less likely to wage unreasonable war upon it. If the farmer is to secure the greatest benefit from telephone service, including all the advances which so constantly improve the quality of transmission, speed of connection, etc., he must at least approach the company in an unprejudiced spirit, and the company on its part must be frank and above board in all its dealings. This applies as much to independent companies as to those of the Bell organization. Candor, plain speaking, openness and a sense of mutual positions will go a long way toward solving the vexing problem of rates.

The Zoelly Steam Turbine.

For a number of years Messrs. Escher, Wyss & Co., of Zurich, Switzerland, well known in this country from the use at Niagara of their water turbines, have been engaged on the development of a steam turbine, of which the accompanying illustration shows the general design.

The turbine, which is manufactured under the Zoelly patents, is of the multi-stage impulse type, in which the expansion of the steam takes place in the passages in the stationary parts of the apparatus. Its main point of difference from others of the type is in the construction of the rotors or bucket wheels, which are intended for high peripheral velocities and require correspondingly few stages. The accompanying elevation of a compound turbine shows its general features. The high and low-pressure ends are mounted independently on a single base. The housings are of cast iron or cast steel, divided on the horizontal plane through their axes so that the upper half can be readily lifted off, and the flanges are fitted so closely that no packing is needed. The details of the mounting have been worked out with a special view to avoiding any appreciable displacement of the axis through temperature changes. The housings are covered with non-conductors and steel lagging.

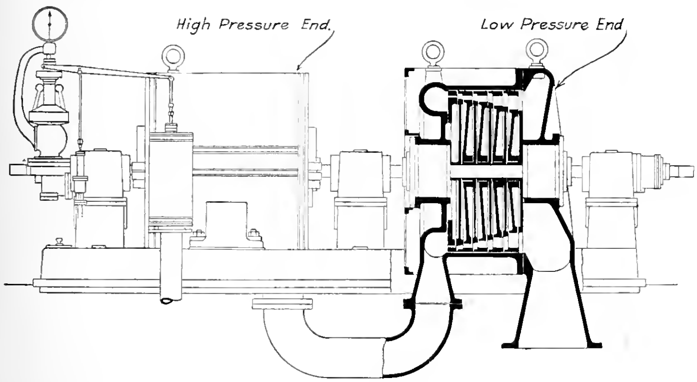

FIG. 1.—ZOELLY STEAM TURBINE.

The three main bearings are supported directly by the frame, and are thus independent of the housings. This arrangement was adopted to prevent any heating of the bearings by the steam or by conduction from the housings, thus keeping them uninfluenced by the condition of other parts of the turbine. They are readily accessible and easily inspected.

A rotary pump placed on the frame and driven from the main shaft by worm wearing supplies lubricating oil to the bearings. The oil from the bearings is piped to a reservoir in the base, where it is purified and cooled in a coil if necessary, and is then ready for use again. In this way, although the lubrication is profuse, the consumption of oil is kept very low.

The discs of the rotors, of the best Siemens-Martin steel, are keyed to the shaft and have fastened on one side of their periphery a thin ring. This ring forms with the periphery of the wheel a dovetail groove in which the buckets and their spacers are held. The radially located buckets are made of nickel steel, polished to reduce friction to a minimum. Nickel steel is employed on account of its resistance to rust. The discs of the wheels are also highly polished to keep down frictional losses.

It is considered of great importance to have the cross section of the blades decrease from their inner to their outer ends. In this way there is correspondingly small tension due to centrifugal action in the roots of the blades, even with high rotative velocity. In other words, with the same stresses the gradually thinning blades can be made much longer than those of uniform section. The resistance to bending, due to the impact of the steam, is greatest where the bending moment is greatest. The strength of the rotor, in consequence of this design, is so great that a high peripheral speed can be attained, and the number of stages correspondingly reduced, as before stated. This enables the length of the turbine to be diminished and its cost reduced. The steel spacing pieces between the blades have their tops coinciding with the curved surface corresponding to the widening of the steam passage between the blades and consequently form an inner limit for the steam jet. The rotors are carefully balanced and tested at speeds above their nominal rates before they are put in place.

Between each rotor there is a guide wheel or diaphragm in which the guide blades are held. Since the expansion of the steam takes place in these diaphragms between the blades and there is a corresponding excess of pressure on one side of them, each must be steam tight in the housing as well as strong enough to resist the one-sided pressure. Cast steel is used, and the guide blades are arranged in groups in the rim, as shown in the illustrations. Between the groups are thick projecting pieces to which a wrought-iron ring or tire is attached. Th diaphragms are placed close together, the rims touching, and in this way the pressure is transmitted to the end wall of the housing. The hubs of the bucket wheels fit with slight play in holes in the bosses of the diaphragms, the construction being evident from the cuts. The blades have small ears which slip into slots in both the rim of the diaphragm and the outside tire. When they have been slipped into place they are held there by two rings screwed on the low-pressure face, as illustrated. These diaphragms are made in halves, with tight-fitting surfaces, and the upper halves are screwed to the top part of the housing so as to be lifted with it. The shaft passes into and from the housing in stuffing boxes fitted with metal packing.

The governor is a slight modification of the well-known Escher-Wyss regulator used in many water turbine installations. It consists of a ball governor which operates a pilot valve controlling the motion of a plunger directly over the main steam valve and mounted on the same rod. The pilot valve and the chamber of the plunger are connected by two small pipes and the various operations are produced by the discharge of water under pressure through one or the other of the pipes. As this governor is one of the best-known water wheel regulators, it is unnecessary to describe it in detail. The pressure water, or oil, in the case of the steam turbine, is furnished by a rotary pump driven from the main shaft by worm gearing. According to Mr. J. Weishäupl, chief engineer of the company, the regulator has behaved excellently in this new service and the variation in rotative speed, even with the maximum fluctuation in the load, is very slight. Regulation by throttling the steam was chosen as being the simplest method for the purpose. In addition it has the great advantage of not influencing the steam consumption unfavorably at different loads.

If it becomes necessary to furnish more than the rated power of the turbine, the governor operates a valve which admits a part of the steam at the throttle pressure directly into the second and third stages. There is also a safety governor which shuts off the steam in case the number of revolutions rises above the normal to a predetermined limit, such as ten per cent.

In impulse wheels the play of the rotating parts in the casing can be made as great as seems desirable, and for the same reason the axial play between the rotors and diaphragms may be made very large without affecting the working of the turbine. Hence, there need be no fear that in consequence of temperature changes or wear the running and stationary parts may rub against each other. It should be stated that a corrugated bearing like a thrust bearing is employed to keep this free play unchanged.

A ten-stage turbine of this type was put in operation at the works of Escher, Wyss & Co. last fall. It is rated at 500 hp per minute at 3,000 r.p.m., with steam at 147 pounds. It is directly coupled to a Siemens & Halske dynamo. A surface condenser driven by an independent steam engine is used. Part of the water for the condenser was taken from the city mains and part was pumped electrically from the works well. This renders it very difficult to determine the power needed for the condensing plant. The unit has

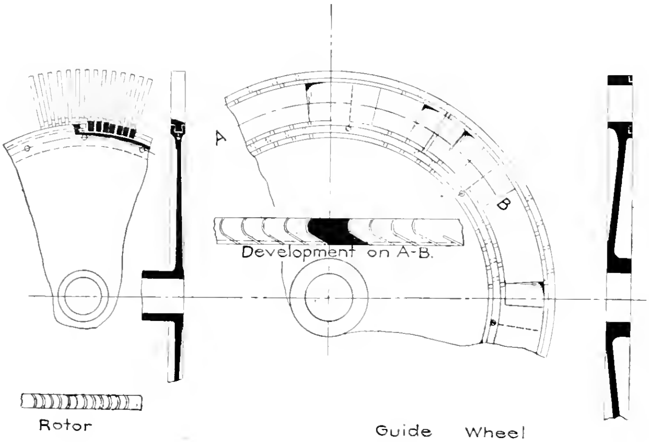

FIG. 2.—ZOELLY STEAM TURBINE.

been tested by Prof. Stodola and Director Wagner of the municipal electric station. They made no attempt to determine the steam consumption of the condenser, and the output of the turbine was figured from the current delivered by the generator. The following statements concerning the test and its results are condensed from their report:

The pressure and temperature of the steam were observed in the main in front of the separator, which is close to the turbine. During the tests with superheating a thermometer was also placed in front of the throttle valve. The pressure and temperature were also measured immediately in front of the first diaphragm and the pressure behind the first rotor was observed, from which data a check on the feed water determinations was obtained. The pressure in the pipe connecting the two halves of the turbine and the pressure and temperature at the entrance to the exhaust main were also observed. The temperature of the cooling water entering and leaving the condenser and the temperature of the discharge from the air pump were measured. The cooling water was only occasionally measured, while the circulating pump was stopped and the supply obtained through a meter from the city mains. The pressures were determined by manometers which, like the thermometers, were calibrated at the mechanical laboratory of the Federal Polytechnic Institute. The vacuum was measured directly by a mercury column, and the heights reduced to their equivalents at 32° F., a correction which seemed necessary on account of the high temperature of the housings. The revolutions were measured every few minutes by a tachometer. Owing to other uses of the steam from the boiler a measurement of the feed water was useless. In consequence, such determinations were limited to weighing the condensed water delivered by the air pump. This was discharged into an elevated reservoir with inclined bottom, from which it flowed to the scales. The net weight of the apparatus was determined after each emptying, since the readings were restricted to ten-minute intervals. On account of the large capacity of the air pump, more frequent weighing would have resulted in less uniform readings. That a steady operating condition had been reached during the tests was shown by the uniform amount of condensation and the constant temperature of different parts of the turbine.

The electrical measurements were made with instruments calibrated by Prof. Weiss, of the physical department of the Federal Polytechnic Institute. A water rheostat was used.

The turbine was first run with a mixture of moderately superheated steam from one source and saturated steam from another. In front of the separator it showed a few degrees of superheat, but this had practically disappeared in front of the throttle valve. The results of the tests are given in the accompanying table. The first eight are with decreasing loads but a constant speed and steam pressure. The tests were at first arranged in the opposite order, beginning with no load, but the temperature readings of different parts of the turbine showed that a steady operating condition would not be reached for hours. The observations made during the eighth of the tabulated tests show this clearly. In this run the unit was first operated at half load for about twenty minutes in order to warm it up, and two hours afterward the temperatures of the exhaust and of the base of the high-pressure housing were still falling. On this account the computation of the steam consumption is based only on the results of the last thirty-five minutes. With heavy loads, a preliminary run of fifteen minutes was sufficient. The last three tests were made with superheated steam. In all of these eleven runs the turbine operated with very litle shaking of the shaft. The oil for the bearings was delivered at a temperature of 86 to 95° F. and came from them at 104 to 122°.

CONDENSED TABLE OF TESTS OF A FIVE-HUNDRED HORSE-POWER ZOELLY STEAM TURBINE.

Iowa State College Branch of A. I. E. E.

In accordance with the desire of the Land and Building Fund Committee of the American Institute of Electrical Engineers that local committees in different parts of the country assist in the work of soliciting subscriptions from Institute members, a committee was appointed by the Iowa State College Branch of the Institute to take up the work in Ames. The committee consists of Messrs. B. S. Lanphear, G. W. Bissell and F. A. Pielsticker. It was decided that each member of the local branch should be asked to contribute something to a joint subscription which should be known as the subscription of the Iowa State College Branch of the A. I. E. E. to the Institute Building Fund.

The committee has been very successful, having raised $700, with several of the local members yet to be interviewed. It is thought that the interest which has thus been aroused in the work of the Institute will materially strengthen the local organization and thus eventually prove of even greater benefit to the local branch than to the Institute Building Fund.

The Iowa State College Branch of the Institute is in a most prosperous condition. The local membership (which includes "students" of the Institute) now numbers 66. The fact that twelve men have made application for admission as associate members of the Institute since the organization of the branch in the spring of 1903 is a measure of the value of this line of Institute activity.

Recent Electrochemical Developments.

ELECTROMETALLURGY.

The amalgamation process is one of the oldest means for winning gold from ores or sands. In its principle it is a purely mechanical operation. An interesting combination of the amalgamation process with electrolytic extraction is described in a patent granted to W. J. and J. J. Jory (May 24). The inventors introduce with the ore to be crushed a solution of mercuric chloride and sodium chloride into the mortars of the stamp batteries; the pulverized mixture is then carried directly through the screens onto the amalgamating tables by a current of water and there subjected to electrolytic action, the amalgamating plates being connected to the negative pole of the supply circuit. The inventors describe in detail apparatus for this purpose and some modifications of this general principle.

An electric furnace process for making aluminum sulphide simultaneously with an aluminum alloy is patented by M. Onda (May 24). The ore containing aluminum oxide is well mixed with charcoal or coke and a metallic sulphide or sulphate whose heat of formation is lower than that of the corresponding aluminum salts. This mixture is subjected in an electric furnace to heat of about 2,000° C. and the aluminum is converted into the sulphide, while the other metal is desulphurized and absorbs a certain quantity of the aluminum which is not sulphurized, producing an aluminum alloy, while the carbon goes off as carbon monoxide. The inventor describes the application of this principle to the treatment of Arkansas bauxite and iron sulphide for the production of aluminum sulphide and a rich aluminum-iron alloy.

ELECTROCHEMICAL METHODS IN ORGANIC CHEMISTRY.

The application of electrochemical methods for the cheaper and often more direct production of organic compounds has been a favorite subject of investigation during recent years, especially in the research laboratories of the larger German chemical works. Two patents of this class were issued on May 31, both being assigned to Boehringer & Soehne in Mannheim.

M. Buchner formerly described a process of electrolytic reduction of nitro compounds, in which the latter were placed in the cathode compartment of the cell and reduced in an acid solution in presence of tin. The tin acts here as a catalyser. He has now found that lead may be substituted for tin, and describes the following two applications: reduction of nitrobenzine to analine by the addition of lead chloride to the catholyte; and reduction of nitrobenzine to analine by addition of metallic lead to the catholyte.

W. Loeb has studied the preparation of azo dyes. Azo compounds are generally prepared by dissolving or suspending an amine in acid solution, diazotizing the same at a low temperature by means of a nitrite, and mixing the diazotized solution with the solution of a "coupling" compound. Loeb has now succeeded in preparing azo dyes electrolytically in one process by combining diazotation and coupling of the amine with a compound of acid character in the same solution under the influence of the current.

BATTERY INVENTION.

There are again quite a number of new patents on batteries; as usual they refer to details. E. W. Smith, of the Electric Storage Battery Company, of Philadelphia, patents a grid having the faces of its respective openings covered by a perforated sheet and describes in detail means for securing the perforated cover plate to the grid.

A. Meygret patents a grid made of an end piece to which various strips are secured, definitely separated one from the other a small distance apart. Each strip has on each outer face a receiving surface for the active material, the receiving surfaces running parallel with the outer side faces of the end piece of the plate.

T. A. Willard patents details of construction of sheaths or envelopes for containing and separating the plates of a battery.

H. P. R. L. Poerscke and G. A. Wedekind patent the following method of making a hard porous metallic (copper) electrode, which is claimed to be insoluble in an alkaline solution. The inventors mix pure oxide of copper and finely pulverized copper with a solution of protochloride of copper without the addition of foreign substances. The pasty mass thus obtained is placed in a mold and heated until dry. The electrode is then reduced to metallic copper in an alkaline solution until all the bound chlorine is set free, whereupon the substance is again oxidized by heating or electrolysis.

New Telephone Patents.

The telephone field is represented by but two patents this week. Of these one covers a receiver support and the other an improvement in a certain form of step-by-step selective system.

The receiver support is the invention of G. A. Cowgill, of Euphemia, Ohio. The supporting arm is hinged so that when the receiver is not in use it will be naturally folded back out of the way. This folding back of the receiver automatically depresses the switch hook; the rearward portion of the supporting arm is pivoted and linked to the switch arm and the position of the center of gravity of the system is shifted across and above the pivot as the receiver is thrown back out of the way.

The selective system improvement refers to a step-by-step system in which automatic return of the selectors at all stations is accomplished by electrical means as soon as the receiver of the last selected station is returned to the hook. With this system as previously designed it has been found that when two party lines have been connected together, the current impulses upon one line might become effective upon the other in a manner to defeat the whole system. For example, suppose *A* of a five-party line connected to *D* of a second five-party line. Both restore the receivers to the hook switches, when upon each line automatically a series of impulses begins, each such impulse moving the selective devices one step toward the zero position. The series of impulses upon each line should decrease when the zero joint of the selector is reached. If, however, there is overlapping from line to line then one selector will be moved past its zero, due to impulses received from the other line. To overcome this certain short-circuiting devices are introduced in the cord circuit as soon as restoration to zero begins. A. J. Springborn, of Cleveland, Ohio, has obtained the patent for this arrangement, which is applicable to a selective system previously invented by him.

CURRENT NEWS AND NOTES.

A LONG TELEPHONE LINE.—The Bell Telephone Company, of Kansas City, has begun preparations for a long-distance line between Kansas City and Joplin, to connect with a new line that is being built from St. Louis to Joplin, and thence through the Indian Territory into central Texas. Over $1,000,000 has been appropriated for these extensions, which, with the Bell connections east of St. Louis, will make the longest telephone line in the world.

MILEAGE OF CANADIAN RAILWAYS.—The report of the Dominion Minister of Railways gives the length of the railways in Canada on June 30, 1903, as 19,836 miles. Of this 19,077 miles were operated by steam and 759 by electricity. The latter includes the street as well as the suburban and general lines, which are growing with rapidity. More than two-thirds of the railways of the country are owned and operated by the government and four companies.

WIRELESS TELEGRAPHY ON THE PACIFIC.—A telegram from San Francisco May 23 says: "For the first time on the Pacific coast communication has been had by wireless telegraphy between a ship at sea and points on shore. The United States hospital ship *Solace* sailed from this port Saturday, and until she was 70 miles out messages were sent between the *Solace* and the Weather Bureau's station at Point Reyes on the mainland and on the Farallone Islands, which lie off this city. Conditions were very favorable, and communication was continued without a break for five hours."

[illegible] WIRELESS TELEGRAPH SYSTEM.—It is stated that Prof. William Hamill, of the Normal Industrial College, at Greensboro, N. C., has invented a simple and practical system of wireless telegraphy, and that it has been tested at the Johns Hopkins Hospital in Baltimore. It is to be installed at the Normal College.

ELECTRIC RAILWAY TESTS.—A comprehensive series of tests is being conducted at the power house of the Lexington (Ky.) Street Railway Company on a storage battery auxiliary recently installed. Prof. W. E. Goldsborough has supervision of the tests, which are being conducted by Prof. A. N. Tapping, of Purdue University, assisted by Messrs. West, Waldron, Hinsley and Goodspeed, students of Purdue. Mr. W. W. Donaldson is present as representative of the manufacturers of the battery, the Gould Storage Battery Company.

IN THE HOSPITAL.—Patients in a hospital often have to endure long, weary hours, and an experiment made recently at the Samaritan Hospital, Philadelphia, suggests a means of beguiling pain and tedium. Through a combination of telephones with megaphones attached to the receivers patients throughout the hospital were enabled to hear the hymns sung at the service in the Baptist Temple, many squares away. The sermon of the pastor was also transmitted to the hospital and was heard as distinctly there as by the people who were occupying pews in the church.

WIRELESS TELEGRAPHY AT THE SEAT OF WAR.—Following the recent manifesto of the Russians regarding wireless telegraphy at the seat of war, a special dispatch from Tokio to the New York *Sun*, a copy of which follows, will naturally excite some curiosity: "It is suspected that the Russians at Port Arthur are communicating with Chinese territory by means of wireless telegraphy, their instruments probably being on some small islands off the coast. The Japanese cruiser *Chitose* discovered four masts showing above Liaotishan, but they were out of range of her guns."

SECOND GERMAN-AMERICAN CABLE.—The laying of the second German cable from Borkum to New York by way of the Azores was completed on Wednesday last week. The cable was laid by the steamer *Stephan*, which left New York on May 10 with 2,100 nautical miles of cable on board. She began to pay out on May 11 from a point off Fire Island. The shore end between Fire Island and Coney Island, where the American end of the cable is landed, had already been laid. The final splice was made off Fayal. The cable was manufactured at Nordenham by the Norddeutsche Seekabelwerke. The total length is 4,200 nautical miles. The first German cable was laid five years ago.

I. E. E. AMERICAN TRIP.—Circulars have been issued to the members of the British Institution of Electrical Engineers outlining the American trip this summer. At present the proposed delegation is not less than 100. It is intended that the party shall leave Liverpool on the White Star steamer *Republic* August 25 for Boston, at which port she is due on Friday, September 2. The party is to reach New York September 4 and start out by special train for the St. Louis Electrical Congress September 6. The total cost, including ordinary extras, is put at $450. A large party from Italy is to arrive directly in New York about August 31. Generous provision is being made on this side at various points for the reception of the visitors from abroad, of whatever nationality. The Congress bids fair to be a great success in attendance and papers.

UNIVERSITY OF MINNESOTA GRADUATING CLASS.—Nearly all of the class graduating from the electrical engineering course at the University of Minnesota are located, many of them being already at work. E. J. Cheney, V. E. Goodwin and F. C. Helms enter the engineering apprenticeship course with the General Electric Company at Schenectady. J. Howatt, F. A. Otto and R. B. Taplin enter the engineering apprenticeship course with the Westinghouse Electric & Manufacturing Company at Pittsburg. L. C. Tomlinson and J. Wicks go with the Automatic Electric Company at Chicago. G. Crahbe goes with the Otis Elevator Company at Yonkers. H. G Morton goes with the Northwestern Telephone Exchange Company at Minneapolis. B. M. Bouman will enter the telephone field P. M. Rosok goes with the Missouri River Power Company at Helena.

NON-RESIDENT ELECTRICAL ENGINEERING LECTURES, UNIVERSITY OF MINNESOTA.—Following is a list of the lectures by practicing electrical engineers, delivered at the University of Minnesota during the college year just closing: Edward P. Burch, consulting engineer, Minneapolis, "Speed Torque Characteristics of Steam and Electric Locomotives"; Lee M. Coleman, electrical engineer, Minneapolis, "Experiences of an Installing Engineer"; Jake Danner, telephone engineer, Western Electrical Company, Chicago, "Telephone Cables"; Charles E. Downton, foreman of apprentices, Westinghouse Electric & Manufacturing Company, Pittsburg, "The Training of Engineering Apprentices in an Electrical Manufacturing Plant"; Locke Etheridge, district engineer, Stanley Electric Manufacturing Company, Chicago, "The Engineer Salesman"; Truman Hibbard, chief engineer, Electric Machinery Company, Minneapolis, "Commercial Features of Dynamo Design"; Charles L. Pillsbury, consulting engineer, St. Paul, "Design and Construction of the Municipal Electric Lighting Plant at New Ulm."

TRACKLESS TROLLEYS IN GERMANY.—Mr. C. L. Cole, United States Consul-General at Dresden, Germany, says: "For several years experiments have been made in Germany with railless electric roads. Among the lines which have come to my notice are several in Westphalia and two in the vicinity of Dresden—the so-called "Haidebahn," connecting with an electric tramway terminus at the outskirts of the town, and the "Königsstein" road starting from Königsstein, a town lying on the Elbe about 12 miles above Dresden. A large proportion of the passengers carried by both lines are tourists or Sunday strollers. The Haidebahn covers a distance of 3.1 miles. Wagons run every half hour, the fares being 10 pfennigs (2.38 cents) for the shortest ride and 20 pfennigs (4.76 cents) for the full distance. The Haidebahn runs over a slightly undulating road, while the one at Königsstein covers about two miles of hilly highway. The speed of coaches varies considerably with the slope of the road, not, it seems, because of a lack of motor force, but for the sake of the comfort of passengers and the reduction of wear and tear on the machinery. It seems that neither of these two lines has proved a marked success from a financial point of view, partly because of the expense in operating. The electric energy required to move cars over dirt roads exceeds by 100 per cent. the power necessary to draw cars over iron rails, and this difficulty should be carefully considered by parties in the United States who contemplate similar enterprises." Another line of this general character, the first in Prussia, is being built between Monnheim and Langenfeld, 2½ miles in length.

Letters to the Editors.

The Metric System.

To the Editors of Electrical World and Engineer:

Sirs:—I have noticed the articles that have appeared in your journal concerning the metric system, and I wish to express my approval of the stand that you have taken in regard to this matter. I am sure that there are many readers of your paper who agree in this statement. Among the older engineers there are of course those who have not learned much about the metric system and who will not favor its adoption; but as sure as the law of the "survival of the fittest" is true, the time is not far off when the system will be adopted in the United States.

Stephenville, Texas. John D. Boon.

Phenomena of the Electric Arc.

To the Editors of Electrical World and Engineer:

Sirs:—I have read with much interest the article appearing in your issue of May 21, 1904, by Prof. Charles Proteus Steinmetz on the new magnetite arc lamp, and the interesting discovery by the General Electric Company at its electrochemical laboratory that the arc is fed by material from the negative electrode and not from the positive, as appearances have heretofore led us to suppose.

In carrying out extended experiments for some months past on my current interrupter, illustrated and described in your columns in November last, I have also observed that the arc flame is fed by the vapors from the negative electrode. I find by replacing the negative carbon electrode by other conducting substances, that the main current does not always readily follow the condenser discharge, while on reversing the current without altering the adjustment of the apparatus in the least, the current follows instantly. Varying the effective area of the negative pole causes a corresponding variation in the current through the gap.

The article in question also states that the great temperature at the positive electrode is due to its being struck by the material from the negative electrode, which issues therefrom at a high velocity. There is a possibility of this statement not being entirely correct, as on this theory the temperature of the negative electrode should equal, if not exceed, that of the positive electrode; for it is reasonable to assume that the negative particles have not acquired any added velocity during their passage through the gap, and also that the greatest temperature is always at the positive pole, no matter what the distances between the electrodes may be.

My theory of the high temperature generated at the positive pole in the ordinary arc is that it is due to local currents set up in the crater by the presence therein of the negatively charged material thrown off or otherwise detached from the negative electrode. I intend in the near future to contribute an article on my experimental observations of the electric arc, but for the present will make this letter suffice.

NEW YORK. THOMAS J. MURPHY.

DIGEST OF CURRENT ELECTRICAL LITERATURE.

DYNAMOS, MOTORS AND TRANSFORMERS.

Direct-Current Dynamo.—WINKELMANN.—An illustrated account of a test of a direct-current dynamo, the feature of which is the construction of the armature. It is shown in Fig. 1. The armature

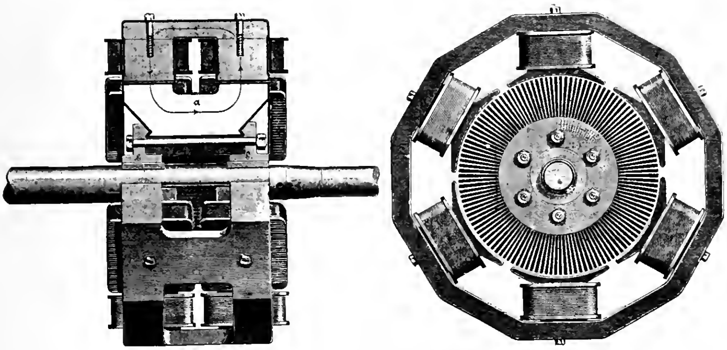

FIG. 1.—DIRECT-CURRENT DYNAMO.

consists of radially-arranged packages of iron sheets, *a*, which are pressed together by means of *b*. The direction of the fluxes in the armature, which is indicated by the arrow, is essentially parallel to the axle and is produced by two neighboring magnet cores. On account of the construction of the armature there are small spaces, δ, which are partly filled by the armature copper. According to the size of the machine, four or more pairs of poles are used. The author thinks that this type has some advantages over the usual type. He tested the machine as motor, the continuous load being 37 kw; the armature current was 151 amp. and the increase of the temperature of the armature 28.7° C. The machine was excited separately with 601 watts and the temperature of the exciting coils was increased by 59°. The voltage at the terminals was 244.5 at 607.7 revolutions. The efficiency was 89.2 per cent. The self-induction of the armature is comparatively low on account of the numerous air-gaps in it. For this reason the commutation was very good, without any sparks either at no load or at full load. There was no shifting of the brushes which were placed in the neutral zone. The author says that the machine could be loaded continuously with 190 amp. without reaching a dangerous temperature, and without sparks at the brushes. The weight per kilowatt was 32 kg. for 33 kilowatts load and 25.2 kg. for 41.8 kw load. The author thinks that this construction of the armature, which was devised by Koppelmann, could be also used for alternators.—*Elek. Zeit.*, May 19.

Repulsion Motor.—HANCHETT.—An article giving from a non-mathematical standpoint the characteristic features of the repulsion motor. Since the repulsion motor is somewhat like a transformer, commutation difficulties can be minimized by winding a motor for as low a secondary voltage as practicable and by the introduction of leads having sensible resistance between the commutator bars and the coils with which they are connected. As one of the best features of the repulsion motor he considers the fact that the speed can be controlled simply by adjustment of the brushes.—*St. R'y Jour.*, May 28.

POWER.

Electric Power in Metallurgical Plants.—The first part of a profusely-illustrated article on electric aerial suspended tramways for quickly transporting materials from one part of a metallurgical plant to another. The system described is that of Kolben & Co. for special use in iron and steel works.—*Elek. Bahnen.*, May, No. 10.

Electricity for Mine Hoists.—An illustrated article on electrically-operated versus steam-driven mine hoists. Some examples from various plants are described. The losses in steam pipes, operating pumps, ventilators, hoists and other mining machinery by engines of small capacity, as well as the low efficiency of these engines, make it desirable to utilize electric power wherever possible.—*Scient. Am.*, June 4.

Lifting Magnets.—PERKINS.—An illustrated article on the construction of Belgian and American electromagnets for lifting heavy pieces of iron and steel.—*Scient. Am.*, June 4.

Steam Turbines.—DRIN.—The first part of an illustrated summary of the development of steam turbines. In the present installment he gives a short history of the subject and then classifies various types of steam turbines.—*La Revue Elec.*, May 15.

TRACTION.

Storage Battery Locomotive.—PASSAUER.—An illustrated article on the use of storage battery locomotives. They are specially useful in switch yards where a trolley line would be difficult and expensive. Compared with a steam locomotive, the storage battery locomotive has the advantage of being always ready for service, and its cost of operation is smaller if the locomotive is used at irregular and longer intervals. The high weight of the batteries is an advantage, since a considerable weight is necessary for adhesion. The author describes the first storage battery locomotive which has been built for such purposes for the Prussian State railways. The battery consists of 200 cells with a capacity of 184 amp.-hours, if discharged in two hours. It is charged once a day. Twenty cells are placed together in a wooden box, which is covered with an acid-proof insulating coating. These wooden boxes are well insulated from each other and from the locomotive by means of porcelain rolls. For charging the battery at 110 volts, the cells are connected in five groups, each of 40 cells in parallel. After the charge is completed the cells are all connected in series, so that an average discharge voltage of 300 to 410 is available. The charge takes place with constant current and with resistance regulation. The controller is arranged for series parallel control. The total weight of the locomotive is 20,840 kg., of which 10,000 kg. is the weight of the battery and 4,340 that of the other electric apparatus.—*Elek. Bahnen.*, May, No. 10.

Berlin.—An illustrated article on recent elevated railway practice in Berlin. He states that the cost of the ornamental Berlin elevated railway was less than $200,000 per km. and describes various experiments which have been made to reduce the noise. Felt was first tried under the rails, then the car wheels were filled with wood; felt was placed on each side of the rails; then experiments were made with ties of steel and wood which rested on fine sand in transverse steel troughs; then the floor planks were lined with cork blocks. None of these methods, however, was so effective as when low rails laid on deep wooden stringers were employed. He gives some particulars on the last track construction and on the car design. —*St. R'y Jour.*, June 4.

Circuit-Breakers on Double-End Cars.—Gough.—An illustrated discussion of the methods available in wiring circuit-breakers. He believes that the parallel connection is the simplest, although requiring two circuit-breakers and two choke coils. The series connection is popular where non-automatic circuit-breakers are used. The trolley connection would not be countenanced in practice, because the motorman on the front end would have no assurance that by throwing the breaker at his end the power would be cut off, as the breaker at the other end of the car might have been left in.—*St. R'y Jour.*, May 28.

Sub-Station.—An illustrated description of a new sub-station of the Denver & Northwestern Railway at Clear Creek Junction, Colo., where two branches of the system join. Current is transmitted to this sub-station at 2,200 volts, three-phase, from Denver, about 9 km. distant. The sub-station is furnished with two six-phase, 25-cycle, 600-volt, 500-kw, 500-r.p.m. rotary converters. The 2,300 to 430-volt transformers are of the air-blast type and are arranged in two banks of three each, delta-connected. Each transformer is rated at 185 kw.—*St. R'y Jour.*, May 28.

REFERENCES.

Mountain Railway.—Armknecht.—The conclusion of his illustrated description of the mountain railway to Hohensyburg, which was already noticed in the Digest. He discusses the rolling stock and gives a description of the electric signal apparatus used.—*Elek. Zeit.*, May 19.

Locomotive Repair Shop Practice.—A communication in which the writer refers to his visit to a large locomotive repair shop. He calls attention to the fact that with the general introduction of electric locomotives much of the complicated machinery now required in railway shops will be unnecessary. He also refers to the matter of fire protection and states that in the shop visited several electric motors were allowed to run exposed to dust, shavings and chips, despite the danger of fire from sparking.—*St. R'y Jour.*, May 28.

Emergency Car Lighting Equipment.—An illustrated description of an auxiliary car lighting system consisting of a number of extra lamps, a storage battery and an automatic switch. The switch and battery are in series with and usually receive current from the regular 500-volt circuit. When the trolley current is interrupted from any cause the switch automatically throws the storage battery into the auxiliary circuit, and as soon as the trolley circuit is restored automatically throws off the current from the auxiliary lighting circuit.—*St. R'y Jour.*, May 28.

Peru.—An article on the first electric railway in Peru, which is about 32 km. in length. Current is supplied from the local lighting station, to which power is transmitted from a hydraulic plant 56 km. distant.—*St. R'y Jour.*, June 4.

Installations, Systems and Appliances.

REFERENCES.

Protection Against Danger from Breaking Overhead Conductors. —Montpellier.—An illustrated description of apparatus, devised by Giraud to prevent the danger from the rupture of overhead electric conductors. He utilizes the mechanical tension set up during rupture in order to set in action a device which makes a short circuit either with the earth or with another conductor, with the result that this short-circuit acts immediately on an automatic interrupter installed at the beginning of the line or of the section. Various applications of this principle are described.—*L'Elec.*, May 21.

Power Station Design.—The first part of a full account of the extended discussion of Merz and McLellan's paper on power station design which was recently abstracted in the Digest. Diagrams are given of the general arrangement of power stations in Edinburgh and Marylebone.—Lond. *Elec.*, May 20.

Wires, Wiring and Conduits.

Eddy Currents in Cable Sheaths.—Addenbrooke.—In the discussion of Field's recent paper on this subject he describes some experiments made by him and intended chiefly to go into the question of dielectric hysteresis. One set of cables had a bare lead sheath and was coiled on drums. An attempt was made to measure the dielectric losses in this concentric cable between the inner conductor and the lead sheath. The losses were, however, so considerable that it was useless to continue the experiment in this form; the lead acted as the secondary of a transformer to a degree that heavy and considerable losses took place in it. This shows that lead-covered cables carrying alternating currents should not be laid in metallic connection with conductors which may form a return circuit. Another observation was as follows: Several measurements having been made on lengths of cable which were unarmored, an armored length was substituted, and in this the losses were uniformly higher than in similar cable made of the same materials, but which was unarmored, the cables being concentric in both cases and the tests taking place between two conductors. At 3,000 volts the power factor was 1.45 per cent., while with armored cable it is 1.62 per cent. In these experiments the current flowing through the cable was merely the current used for electrostatically charging it, and consequently the effect would be very small. With the actual currents flowing in practice through the cable it is quite possible that the effects might be very appreciable. The only way to determine them would be to take a length of cable having a non-inductive resistance at one end in which the energy of the current passed through the cable would be dissipated. If then a steady alternating current was passed through the cable and simultaneous measurements could be taken at both ends, both of the current and watts lost, deducting the calculable loss in the conductor of the cable it ought to be possible to arrive at any other losses which may take place.—Lond. *Elec.*, May 20.

REFERENCE.

Power Transmission Cables.—Schmidt.—The conclusion of his long illustrated serial on the construction and manufacture of power transmission cables. He gives some diagrams showing the increase of the total weight and of the cross-section of cables with increased voltage of supply.—*Elek. Anz.*, May 19.

Electro-Physics and Magnetism.

Secondary Röntgen Radiation.—Barkla.—An account of an experimental investigation of the energy of secondary Röntgen radiation. The character of secondary X-radiation from gases differs slightly from that of the primary producing it (from air the secondary has a great ionizing power in air). The penetrating rays are transformed to a greater extent than the more absorbable rays. The energy of secondary radiation from a given gas through which a primary beam of given intensity is passing is independent of the character of the primary radiation. The energy of secondary radiation from gases and those light solids which are the source of the radiation differing little in character from the primary, is proportional to the quantity of matter through which the primary beam of given intensity passes. In the passage of X-radiation through air at zero degrees C. and at 76 cm. of pressure, the diminution of intensity due to secondary radiation is of the order of magnitude 0.02 per cent. per centimeter; this is a large fraction of the total loss of intensity due to all causes for fairly penetrating rays. Applying the experimental results to the explanation given by J. J. Thomson for the loss of energy per centimeter (due to radiation) in passing through a medium containing ions, and taking the negative corpuscles with $e/m = 7 \times 10^6$ and $e = 10^{-20}$ as the sources of the radiation, the number of these corpuscles per c.c. for air under normal conditions is of the order 10^{22}. Quantitative results show that the secondary radiation for metals, though of different penetrative power, is of the same nature as the primary X-radiation.—*Phil. Mag.*, May.

ELECTRO-CHEMISTRY AND BATTERIES.

Metallurgy of Gold in South Africa.—DIXON AND TORRENTE.—A very complete account of the development of the metallurgy of gold on the Rand gold fields. The first mill, consisting of only five stamps, was installed in 1887; in 1890 the chlorination process and the MacArthur-Forrest cyanide process were introduced. The introduction of the latter revolutionized the whole aspect of the industry and enabled many low-grade propositions which could otherwise never have been worked at all to pay handsome dividends. The authors give a review of the treatment of sands and slimes and deal at length with the problem of precipitation. In 1894, when the Siemens & Halske electrolytic process was introduced, its main advantages were that a 2 per cent. royalty was charged and that very weak cyanide solutions could be used, while for the zinc precipitation process a 10 per cent. royalty was charged and very strong solutions were used. Later, however, the MacArthur-Forrest patents were upset and the consideration of a 10 per cent. royalty was no longer a factor in the case. The great rivalry between the advocates of both processes resulted in many improvements. The zinc precipitation process was especially improved by the introduction of the zinc-lead couple with the addition of a strong free cyanide solution at the head of the precipitation boxes, according to Betty's suggestion. The authors then give a great many details on the working of the Siemens & Halske electrolytic process by which in 1903 were treated 239,385 tons of sands or tailings which produced 54,794 ounces fine gold; and 129,137 tons of slimes which produced 17,370 ounces fine gold. At present the zinc process seems to have slight advantages, but even now the variations in costs and results between the two processes are very slight, and although at present the zinc process shows a slightly better average in precipitation, the opportunities for losing gold throughout the various operations before eventually producing a lead bullion for cupelling (which is obtained first hand in the electrolytic method) must go a long way toward counterbalancing its advantages. The ideal process which is still sought is one that will precipitate gold from its solution down to say 4 grains per ton with a moderate-sized plant, will produce no by-products, and a bullion bar must be obtained in a simple manner and of a high standard of fineness. The authors then discuss the treatment of the by-products.—*Electrochem. Ind.*, June.

REFERENCE.

Electrolytic Process for Winning Copper from the Ores.—THOMPSON.—A full account of an extended investigation of the Siemens electrolytic process for winning copper from the ores. He first discusses the dissolving action of ferric sulphate on various copper compounds; he describes experiments made with cupric oxide, cuprous oxide, cuprous sulphide, iron oxide and a natural copper ore. He finds that copper pyrite is not appreciably attacked by ferric sulphate; roasting so changes the ore that nearly all the copper can be extracted either by sulphuric acid or by ferric sulphate; this makes it seem probable that roasting changes the copper largely over to the oxide. He then discusses the electrolytic part of the process and deals separately with the reduction of the copper on the cathode and the oxidation of the iron at the anode. The results are given in diagrams and tables.—*Electrochem. Ind.*, June.

UNITS, MEASUREMENTS AND INSTRUMENTS.

System of Units.—KENNELLY.—A communication referring to the recent suggestion of Robertson. He first remarks that it is open to question whether the c.g.s. electromagnetic system is really based, as assumed by Robertson, upon four fundamental quantities, namely, length, mass, time and magnetic permeability. The c.g.s. system is rather based only upon length, mass and time, while permeability is thrown in at present because its dimensions in terms of the other three quantities are not yet determined. As soon as the dimensions of permeability are realized, the term will disappear in the modification of the dimensions of the units where now it comes in evidence. He also thinks that it is now too late to uproot the c.g.s. system and replace it with the meter-kilogram-second system.—Lond. *Elec.*, May 20.

Fessenden.—A communication in which he expresses himself strongly in favor of rationalizing the units by taking the ampere current as the unit difference of magnetic potential and the magnetic line as the unit of magnetic quantity. This will give a rational system and will entirely eliminate irrational quantities from our present calculations. He pleads that every effort should be made at present to rationalize the units; if this should be impossible, no effort must be spared to prevent the establishment of legal units of magnetic potential and of magnetic quantity. If the present theoretical units—i. e., 4π magnetic lines—be made the unit of quantity, the $\frac{1}{4}\pi$ ampere-turns be made the unit difference of magnetic potential, we will cut ourselves off absolutely for several hundred years from having a set of rational units. There is no necessity of manufacturing names for the physical quantities, because if we write these physical quantities in terms of their dimensions, with a suitable prefix to denote whether the quantity is an electric, magnetic or a gravitational one, we get names which have the advantage that they not only uniquely describe the quantity, but also give its dimensions.—Lond. *Elec.*, May 20.

Thermal Instruments for the Measurement of Large and Small Alternating Currents.—DUDDELL.—A British Physical Society paper describing three thermal instruments. The first is essentially a sensitive Ayrton-Perry twisted strip ammeter which is very quick in action for a thermal instrument and has been used for observing and recording potential differences and currents which varied as rapidly as one per second. It is compensated for change in the surrounding temperature by forming the sides of the frame which holds the twisted strip with the same wire that the strip itself is made from. He exhibited an instrument which for a current of 22 milliamperes gave a deflection of one-quarter of the scale distance, i. e., 250 mm. at one meter scale distance. The mechanical periodic time is only about $\frac{1}{5}$ second. Using this instrument in series with a high resistance, he has made observations on the variations in the voltages of alternators caused by cyclic irregularity of the engine. By working to a false zero it is easy to obtain 10 mm. change in deflection for one per cent. change in the potential difference. The second instrument described by him is called a thermogalvanometer. It consists of the combination of a ratiomicrometer of the Boys type with a very small resistance which is heated by the current to be measured, and which in turn heats the thermojunction of the radiomicrometer by radiation and convection. The principle of its action is as follows: A loop of wire has its two ends fixed to the two bars of a single thermojunction, a mirror is fixed to the loop and the whole is suspended in a magnetic field by means of a quartz fibre. The heat from the resistance raises the temperature of the thermojunction and causes the current to flow round the loop, which is deflected by the magnetic field. The sensibility of the instrument depends upon the resistance of the heater. Using a heater having a resistance of 13,910 ohms, a deflection of 250 mm. at a scale distance of one meter is obtained with a current of 31 microamperes; a heater having 18 ohms resistance required 800 microamperes to give the same deflection. To illustrate the high sensibility of this instrument, the author showed the large deflections produced by the currents through a telephone receiver even when the source of sound was many feet distant from the microphone. He also showed that if the thermogalvanometer was placed in series with the vertical receiver wire in spark telegraphy over a short distance, large reflections were produced. The third instrument described is a switchboard instrument which works on the same principle as the last, only that the moving part is pivoted in the usual way. He exhibited one of these instruments arranged to give the whole scale deflection for only 0.15 volt, which can be used in connection with shunts to measure large currents; for instance, to measure 1,000 amperes the power lost in the shunt would only be 150 watts. Transformers can also be used, as the power to produce the whole scale deflection is only 0.3 watt. A similar instrument with a high resistance heater was also exhibited, giving the whole scale deflection for 0.1 amp., which can be used as a voltmeter by putting resistance in series with it.—Lond. *Elec.*, May 20.

Induction Coils.—CODD.—The first part of an illustrated article in which the author discusses various details of induction coil design.—Lond. *Elec. Rev.*, May 20.

TELEGRAPHY, TELEPHONY AND SIGNALS.

Telephony.—BENNETT.—A paper on corporation telephones in which the author gives a review of his work in this direction, together with a report of the extended discussion which followed the reading of the paper.—Lond. *Elec.*, April 22, May 20. An editorial with reference to this paper gives a comparison of telephone systems. Concerning the central battery system, it is said that its one doubtful feature is its complexity; numbers of relays have to be employed and the efficiency of the service depends to a large extent on the proper working of a chain of automatic devices. From remarks of Gill in the discussion it appears that no serious troubles arise from relay faults in practice. The writer thinks that there is much to say in favor of the simple magneto system with branching multiple switchboards, for exchanges of small and moderate size. Automatic calling and clearing introduces a considerable complication, but for some reason it has come to be regarded as an essential to modern exchange systems. Even Bennett considers it of such importance that he introduces into his simple "ring-through" system the automatic feature with the aid of a "passing contact" in the subscriber's instrument. Then comes the substitution of an incandescent lamp and a relay for the drop indicator, which is justified by the saving of space on the switchboard, and still more by the increased facility for supervision. After one has gone so far as to make provision for automatic calling and clearing, and for lamp signals, very little more is required to make the system a complete central battery system, with central battery speaking, as well as central battery signaling. The writer thinks that for small exchanges these refinements are certainly not necessary, but a uniform system throughout is very desirable. The old principle that an endeavor should be made to lessen the operator's work by making the subscriber do part of the operating, as on a call-wire and ring-through system, has not been found to work out well in practice. The greatest drawback is with junction working, in case of a failure to ring off.—Lond. *Elec.*, May 20.

Alarm Bells Tuned to the Strength of Direct Current.—BAUMANN. —An illustrated description of various devices of this kind, which appear to be specially suitable for calling up only the one party desired out of a number of parties connected to the same telephone wire on a "party line." The simplest arrangement is shown in Fig. 2. The electromagnet, *a*, has two windings, *b* and *c*; *b* is connected

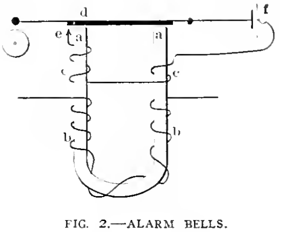

FIG. 2.—ALARM BELLS.

to the line while *c* is connected to a circuit containing a battery, *f*, and the armature, *d*, of the electromagnet as soon as the contact, *e*, is closed. The two windings, *b* and *c*, are so arranged that the magnetic fluxes due to them counteract each other. When a current of sufficient strength passes through *b* the armature, *d*, is attracted and the contact, *e*, is closed; then the magnetism is annihilated, due to the counteracting ampere-turns of *c*, and the armature is released. Then *b* acts again, and so on. The armature bears at its terminal a clapper which strikes the bell so that it will ring. No ringing of the bell will take place if the current through *b* is too small to attract the armature, *d*. On the other hand, in the case that the current is beyond a certain limit, the armature will be attracted by the current passing through *b*, but *c* will not be able to produce a sufficient counteracting magnetic flux and the armature will not be released. There will, therefore, be a single click, but no real ringing of the bell. If one connects four of such devices in series in the line and four more, identical to the first four, in such a way that the current passes through them in the opposite direction, it is possible to operate without difficulty eight bells in the same line with say 30, 60, 90 and 120 milliamperes. A considerable number of such devices is in use in German party lines for telephony. It is stated that the devices are not very sensitive against variations in the insulation of the line. One disadvantage of this device is that when, for instance, the one bell tuned to 120 milliamperes is set into action, the armatures of the others are also attracted and produce a click on the bell. While the bell does not ring, yet the click is a disadvantage. To prevent that another arrangement is used, the principle of which is shown in Fig. 3. The principal point is that each electromagnet has two armatures, *d* and *f*, which together form a contact. In Fig. 3 three such devices are connected in series, *c* representing the electromagnets, *h* batteries and *i* galvanometers. The springs, *e* and *g*, hold the armatures *d* and *f* in the position shown in the illustration. If a current of strength one passes through the line, it will attract in the first elec-

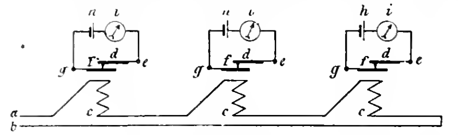

FIG. 3.—ALARM BELLS.

tromagnet the armature *f* and will disconnect *f* from *d*, but will not be sufficient to attract the armatures, in the other devices. If a current of a greater strength 2 passes through the line, the armature, *f*, in the second device will be attracted and the contact between *d* and *f* will be broken. On the other hand, in the third device the current is not strong enough to attract *f*, while for the first device the current is so strong that both armatures, *f* and *d*,

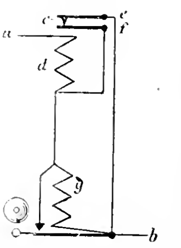

FIG. 4.—ALARM BELLS.

are attracted. Neither in the first nor in the third device the contacts between *d* and *f* are, therefore, broken so that only in the second device, which is tuned to the current sent through the line the contact between *d* and *f* is broken. This principle is applied as shown in Fig. 4. *a b* is the line, *d* is the electromagnet with a double armature mounted on the springs, *e* and *f*, and forming the contact *c*, while *g* is an electromagnet which when magnetized acts on a bell. If the current in *d* is too small the double armature, *c f*, remains unmoved and the current passes along the path *a d c e b*. If the current becomes sronger, the armature, *f*, is attracted and the current passes along *a d g b* and the bell rings. If the current is strong enough to attract both armatures, *e* and *f*, the current passes along *a c e* and *b*.—*Zeit. f. Elek.* (Vienna), May 15.

New Books.

ELEKTRO-AKUSTISCHE UNTERSUCHUNGEN. By Robert Hartmann-Kempf. Frankfurt: Gebruder Knauer. 255 pages, 105 illustrations.

This volume is remarkable as a book, for its clear type, good paper, careful proofreading and singularly beautiful photographic plate reproductions. It contains the results of the author's researches set forth as a doctorate thesis on the physical subject recited in the sub-title, namely, the influence of amplitude upon the pitch and decrement of tuning forks and tongue-shaped steel strips. The entire work bears the impression of careful experimenting and faithful recording.

A number of interesting physical data are developed from the experiments set forth in detail. The effect of the atmospheric pressure in lowering both the pitch and sustenance of both strip springs and tuning forks is abundantly evident. The change in pitch or frequency was in the neighborhood of one-tenth of one per cent. between full atmospheric pressure and a good vacuum, while the logarithmic decrement was reduced by the vacuum about three times.

The sharpness of the mechanical resonance to electromagnetic excitation was also well demonstrated. The application of this principle to the purpose of frequency measurement in the well-known apparatus of this type is immediately evident. The book will be of great value to the student of electromechanical resonance or of acoustics.

Electrical Interests in Panama.

The government of Panama has granted the United Fruit Company a fifteen-year concession for the operation of a system of wireless telegraphy between Panama, Colon, Bocas del Toro and the Bay of Limon and the Central and South American nations. The concession is now being discussed in the legislature, and will probably be approved.

The electric light and tramway plants and the telephone system in the Panama Canal zone have been bought by a syndicate, in which American capital is interested.

St. Louis Exhibits of the Westinghouse Companies.

The main service plant at the Louisiana Purchase Exposition, for which the Westinghouse Electric & Manufacturing Company received the general contract, is naturally a notable feature of the Westinghouse exhibits, and one which appeals, because of the commanding size of the four big electric generating units, each of 2,000-kw capacity, and their location in the central aisle of Machinery Hall, to practically all visitors to the Fair. These generators operate at a speed of 83½ r.p.m. and deliver 25-cycle, three-phase current at 6,600 volts. Entrance to the service plant exhibit is through a large 35-ft. plaster ring molded in close representation and in exact duplicate size of the stationary armature of the 5,000-kw alternating-current Westinghouse generators constructed for the elevated and subway train service in New York City. In this connection it may be said that 10,000-kw generators for the Ontario Power Company are now being constructed in the East Pittsburg works of the Westinghouse Electric & Manufacturing Company.

There is little in common in the Westinghouse Chicago service plant of 1893 and the St. Louis service plant of 1904, save the name of the manufacturer. At Chicago six of the twelve 750-kw generators there used were driven direct by Westinghouse-Columbina steeple engines, the other six being belt-driven to various types of engines, the space occupied by the smallest of the belt-driven generating units complete being about 65 by 27 ft. The units at St. Louis, almost three times as large, are direct-driven, of course, and the space occupied by each over all, with the 36-in. by 76-in. by 54-in. Westinghouse Corliss vertical cross-compound engines, is only about 35 by 15 ft., and 32½ ft. in height, the fly-wheels being 23 ft. in diameter.

The total space devoted to the service electric plant in Machinery Hall, with the exciter units, condensers, cooling towers and the 35-panel switchboard, is 26,260 sq. ft. The entire steam and electric station was designed and equipped by Westinghouse, Church, Kerr & Co., and all the motive power apparatus in connection with the generators, and in the steam generating plant in the nearby boiler house, was furnished by the Westinghouse Machine Company. The electric plant, although within the Westinghouse walls at the west end of Machinery Hall, has not been laid out on elaborate lines to combine the diverse characteristics of exhibition and service, and is an exhibit plant only in so far as it is representative of thoroughly modern practice at minimum cost. The various organizations associated with the Westinghouse name, which have united in representation at St. Louis under the title of the "Westinghouse Companies at Louisiana Purchase Exposition," have additional adjoining exhibit space in Machinery Hall of 26,260 sq. ft., space in the Palace of Electricity of 10,100 sq. ft., where Baldwin-Westinghouse electric trucks and locomotives also are shown, and space in the Palace of Transportation of 3,000 sq. ft., a total of 65,620 sq. ft., or nearly ten times the space occupied by the same interests at the Pan-American Exposition at Buffalo in 1901. The organizations associated in these joint exhibits, which represent an army of 30,000 employees, and occupy a total workshop floor space of over 140 acres, more than is found in all of the twelve great exhibition palaces of the St. Louis Exposition, are as follows:

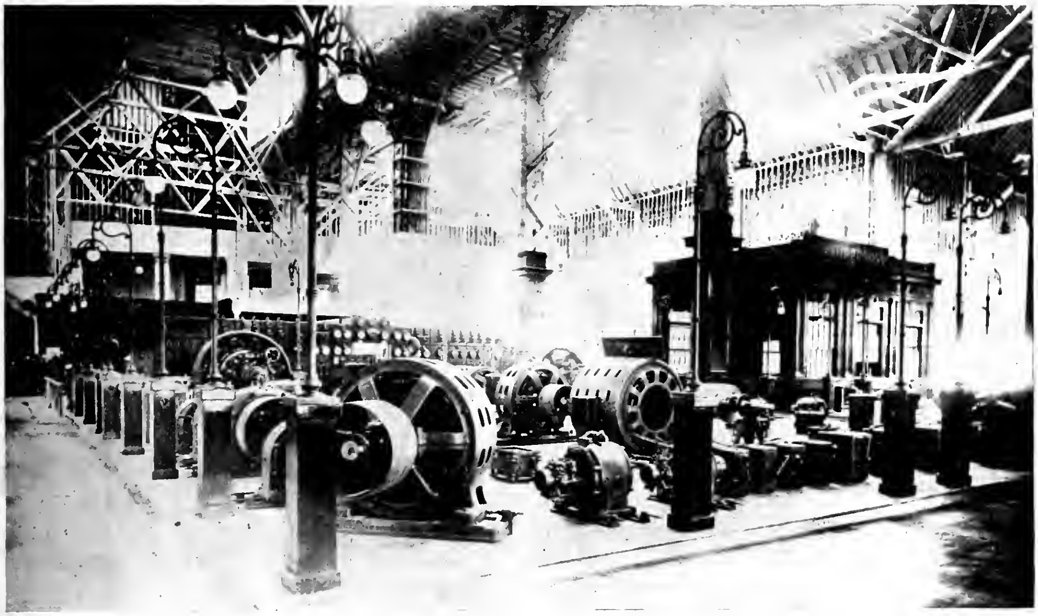

FIG. 1.—CORNER VIEW—PART OF WESTINGHOUSE ELECTRIC EXHIBIT, PALACE OF ELECTRICITY.

Westinghouse Electric & Manufacturing Company, Westinghouse Machine Company, Westinghouse Air Brake Company, Westinghouse, Church, Kerr & Co., Westinghouse Brake Company, Limited, London, Paris and Hanover; British Westinghouse Electric & Manufacturing Company, Limited, Westinghouse Automatic Air & Steam Coupler Company, Westinghouse Traction Brake Company, Canadian Westinghouse Company, Limited, Société Anonyme Westinghouse, Havre, France; Société Anonyme Westinghouse, St. Petersburg, Russia: Westinghouse Electricitäts-Actiengesellschaft, Berlin; Sawyer-Man Electric Company, Union Switch & Signal Company, American Brake Company, Nernst Lamp Company, Pittsburg Meter Company, R. D. Nuttall Company, Cooper Hewitt Electric Company, Bryant Electric Company, Perkins Electrical Switch Manufacturing Company.

In Machinery Hall, in addition to the electric service plant and the main exhibit of Westinghouse gas engines, turbo-generators, rotaries, exciters and motors in operation, all enclosed within ornamental staff walls and columned entrances of classic design, is the

Westinghouse auditorium, which seats 350 persons, in which are displayed at regular hours through the day the biograph and mutoscope pictures of scenes in and about the various Westinghouse works in the Pittsburg district, including the first interior photography of the kind ever taken by means of the Cooper Hewitt mercury vapor lamp. Through the courtesy of the companies, this auditorium, which is of ornate architectural design, rendered cool and comfortable at all times by a ventilating system which provides a continual supply of pure air and brilliantly lighted by the four principal systems of electric illumination, will be used throughout the Fair as a meeting place for scientific societies and technical congresses. The lighting of the hall is with the incandescent lamps of the Sawyer-Man Electric Company, Bremer arc lamps, Cooper Hewitt mercury vapor lamps and the Nernst glowers, all of which are used extensively throughout the Westinghouse display.

The Cooper Hewitt lamps, which made possible the Westinghouse mutoscope shop views, one of the distinct novelties of the Fair, are shown in the booths in Machinery Hall and in the Palace of Electricity, as designed for use in general illuminating, photographing and photo-engraving, with samples of work by some of the best operators in the latter lines. Demonstrations of the lamps will be given for the benefit of the National Photo-Engravers' Association at its June convention, and for the convention of the National Photographers' Association in October. The lamps are in use on the grounds by the official photographer, and in an illuminated sign of the Robbins Conveying Belt Company, in the Pike shows, "Over and Under the Sea" and the "German Tyrolean Alps"; and in various exhibits, and never fail to excite comment. The most striking use of the lamp, however, is in the eight-foot tubes which are hung over the entrance to the Westinghouse auditorium, and over the entrance to the Cooper Hewitt booth in the Palace of Electricity.

There are in all about 10,000 Nernst glowers in use in the exhibition buildings, 6,000 of them in the Fine Arts Museum, where they effectively solve the problem of artistic illumination. The handsome Illinois State Building is lighted by them, the National Cash Register Company uses the glowers in its three displays in the Liberal Arts, Electricity and Education Buildings, and the Westinghouse Companies use 300 big street glowers in their exhibits. Westinghouse generators are supplying current to the Nernst glowers throughout the Fair, as well as to the 200,000 incandescent lamps which outline the capitals, towers and general architectural design of the buildings in the charming night illumination. On exhibition or in service the Westinghouse Companies have installed within the Exposition grounds 14,000 hp in generating machinery and 30,000 hp in other apparatus.

The Sawyer-Man Company's display of various types and sizes of its well-known incandescent lamps is in the general Westinghouse exhibit space in the Palace of Electricity. There, also, the Bryant Electric Company shows a variety of lamp sockets, receptacles, switches and other products, including details manufactured by the Perkins Electrical Switch Manufacturing Company. The R. D. Nuttall Company's exhibit of cut and planed gears, trolleys, trolley gears and pinions, for electric railway, mine and industrial haulage motors, is in Machinery Hall, near the Westinghouse headquarters.

The Pittsburg Meter Company has a separate booth in block 35 of Machinery Hall. There the Keystone water meters and parts, with Westinghouse fish traps; Westinghouse gas meters, water meter provers, and a Westinghouse proportional 12-in. gas meter of the new straight-line type, with a capacity of 100,000 cu. ft. an hour, are shown. A graduated assortment of Keystone water meters on a revolving pyramid frame, with a 6-in. meter at the base and a ½-in. meter at the apex, constitutes the moving feature of the display.

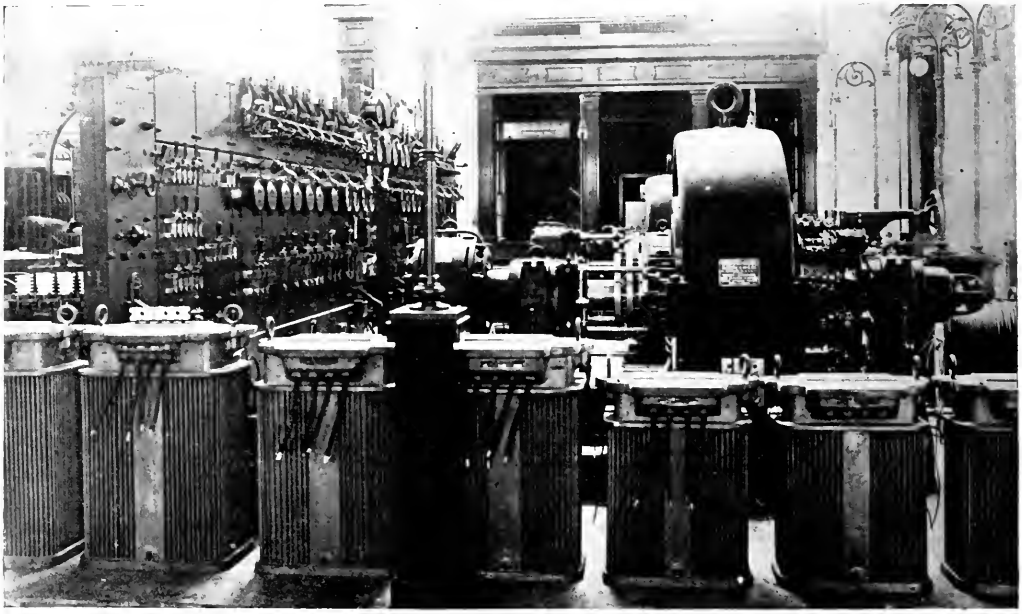

FIG. 2.—PART OF WESTINGHOUSE EXHIBIT, PALACE OF ELECTRICITY —SERVICE TRANSFORMERS, SWITCHBOARD AND ROTARY CONVERTERS.

Steam for the Westinghouse electric service plant is piped from the boiler house, known as the Steam and Fuels Building, nearby, in which there has been installed under the direction of the same engineers and contractors, a large battery of Babcock & Wilcox water tube boilers built into a single setting, with a total capacity of 6,400 hp. Equipment here includes also Roney mechanical stokers at the furnaces, operated by Westinghouse standard steam engines, a complete coal-conveying system furnished by the Link Belt Engineering Company, Cochrane feed water heaters, Worthington steam pumps, mechanical draft condensers, cooling towers and other apparatus to be found in a model station of the present day. The auxiliary apparatus in the electric plant includes three 80-kw, direct-current, 125-volt, direct-connected engine-driven exciter units, two of which are sufficient to operate the entire plant and adjacent auxiliary machinery in the exhibit sections. Each of the four chief generating units receives steam from a separate line, supplied by a separate battery, the entire plant thus consisting of two sections which may be operated independently or together.

The exhibit service plant, immediately west of the companies' headquarters, is utilized to furnish power for various purposes, and includes a Westinghouse-Parsons steam turbine generating set of 400-kw capacity, operating at a speed of 3,600 r.p.m., and delivering three-phase, 60-cycle currents at a potential of 440 volts. The unit selected for exhibit is of a size that has met with most extended introduction by reason of its applicability to power stations of moderate size, and at the present time is the smallest turbine unit built by the Westinghouse Machine Company, a number now nearing completion being of 7,500-hp capacity. The construction of the rotating field of the generator shown in connection with the turbine on exhibition may best be studied in the Westinghouse exhibit in the Palace of Electricity, where one of similar type is set up, but not in operation. The exhibit service plant contains also a 125-hp vertical and a 225-hp horizontal gas engine, the first direct-connected to standard two-wire, the second to standard three-wire, double-voltage, direct-current generators. Both single-acting and double-acting types of gas engines at present manufactured by the Westinghouse Machine Company are here represented in their latest form. The horizontal engine may be regarded as strictly representative of the modern internal combustion motor in its most recent development. Here, again, the gas engine unit on exhibition is one of the smallest built in its particular type, engines up to 3,000 hp now being under construction in the Westinghouse shops.

An important part of the Westinghouse installation which is seen by few is the pumping apparatus under the beautiful Cascades in front of Festival Hall. This equipment was designed to supply 90,000 gallons of water a minute for these Cascades, by three large centrifugal pumps each driven by a 2,000-hp Westinghouse induction motor, probably the largest motors ever constructed. The famous "Jumbo" engine which alone operated all the machinery of the Philadelphia Centennial Exposition in 1876, was rated at 1,000 hp. Here,

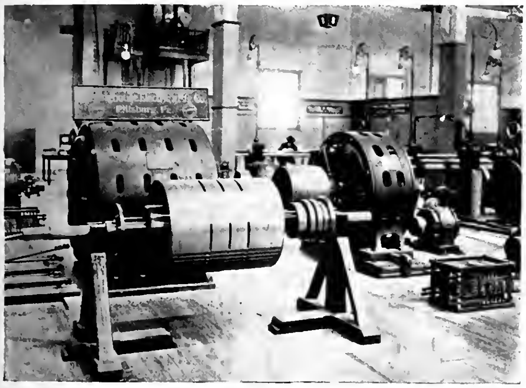

FIG. 3.—REVOLVING FIELD AND STATIONARY ARMATURE OF TURBO-GENERATOR SET, PALACE OF ELECTRICITY.

in a single plant, operating but one feature of the St. Louis Fair, is machinery with six times that capacity.

In the Palace of Electricity the Westinghouse Electric & Manufacturing Company occupies a space of over 10,000 sq. ft., including 1,600 sq. ft. devoted to the display of electric trucks and locomotives constructed in conjunction with the Baldwin Locomotive Works. Two locomotives built for mine service are shown, one weighing 20,000 and the other 30,000 pounds, each equipped with two No. 79 motors at 500 volts. Another 20,000-pound locomotive, for switching, is equipped with two No. 75 motors at 220 volts. In the regular electrical equipment display are a 400-kw turbine type generator, typical generators for direct and alternating currents, for belt or direct connection; rotary converters, motor-generator sets, oil-insulated and air-blast transformers, direct-current and alternating-current railway motors and controllers, single and polyphase induction motors of constant and variable speeds, direct-current motors of many types, including motors for variable-speed service from single and double-voltage circuits, switchboard apparatus, ammeters, voltmeters, wattmeters, synchroscopes, power factor meters, circuit-breakers and switches, many of them electrically operated; portable instruments, instruments of precision, potential regulators, and innumerable other forms of auxiliary apparatus and instruments. The alternating-current, series-wound, single-phase crane motors, similar in type and general construction to the single-phase railway motors exhibited in the Transportation Building, and the new "Westinghouse Unit Switch System of Multiple Control" are also to be seen in this section. The spectacular high-tension sign, using a potential of 50,000 volts, which spells the name "Westinghouse" in lightning-like discharges radiating from large letters over a plate glass surface—one of the attractions at the Pan-American Exposition—is to be seen in the Westinghouse auditorium.

The combined exhibit of the various Westinghouse brake companies extends for 150 ft. down the aisle from the turn table in the Transportation Building. At the end nearest the turn table is a reception room for guests, and at the other end is a booth fitted up

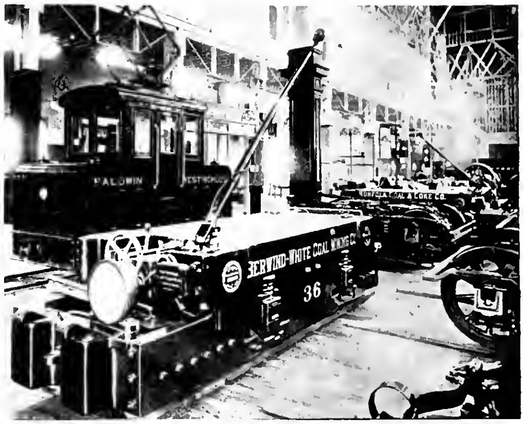

FIG. 4.—BALDWIN-WESTINGHOUSE ELECTRIC LOCOMOTIVES, PALACE OF ELECTRICITY.

as a Russian kiosk by the Westinghouse Company, Limited, of St. Petersburg, to be used as a rendezvous for Russian visitors to the Fair. Included in this operating exhibit is the display of the Westinghouse Electric & Manufacturing Company's alternating-current, single-phase railway motors, now so prominently before the engineering world, and which are introducing radical changes in present railway practice.

The Westinghouse Air Brake Company's exhibit shows a rack made up of apparatus constituting the equipment for a six-coach passenger train with engine and tender, all fitted throughout with the high-speed brake and signal equipment. The engine and tender are equipped also with the combination automatic and straight air

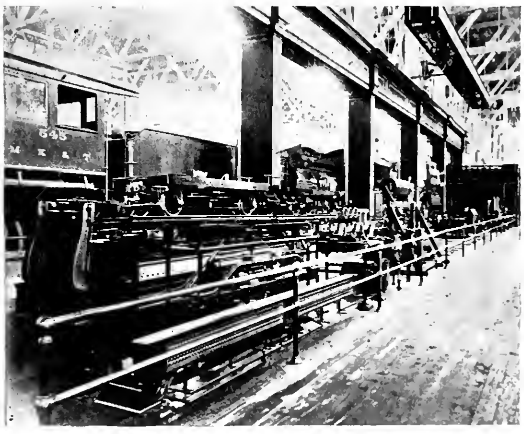

FIG. 5.—BRAKE EXHIBITS, TRANSPORTATION BUILDING.

brake which is now so much in use. The method at present generally adopted when two pumps are used on one locomotive is shown, and one of the novel features of the rack is that all valves are placed in duplicate, one sectioned so as to show the internal working mechanism, and connected to the valve in use in such a manner that it moves as the regular valve is operated. The operation of the various valves is thus readily studied.

The Westinghouse friction draft gear also is shown in section, with a machine especially designed for testing it in operation. The available power which can be exerted on the draft gear approximates 2,000 pounds. A triple valve testing rack is presented to show the manner in which this device is now being installed in many railroad shops. Sectional parts also are shown of the other apparatus of the Westinghouse Air Brake Company and the Westinghouse Traction Brake Company. The latter's exhibit consists of the magnetic brake and car-heating apparatus and the straight air brake for both motor-driven and axle-driven compressors. The magnetic brake is applied to a truck operated on a track 45 ft. long, the truck being equipped on both ends with friction draft gear buffers, showing the use of this device which has become extensively adapted to this kind of service. In this connection also is shown the separate brake controller for use with the magnetic brake when it is decided to add the latter to street railway equipment having the ordinary controller for the motor.

The straight air brake rack shows the equipment now used in the straight air outfit on electric cars that are operated by one of their standard compressors. The compressors shown are of the axle and motor-driven types, in section for inspection of their internal working parts. One of the sectional compressors is fitted to move with a regular compressor in operation.

Swinging picture frames are hung from a pipe frame to show photographs and colored instruction charts which adequately portray the equipment made by the Westinghouse Traction Brake Company, the colors representing the different pressures during the operation of the brake. In the exhibit of the American Brake Company is shown a model of the outside equalizing brake for locomotives, and the American automatic slack adjuster. The Westinghouse Automatic Air & Steam Coupler Company shows the ends of two freight cars fitted as movable models to show the operation of the device in actual practice. This also is shown on two small models fitted with air and steam and signal coupler. Under this model is another working model of the magnetic brake, arranged to show the operation of the device.

The Union Switch & Signal Company's exhibit is a group of signals, full size and in working condition, erected in the Transportation Building. The company shows also examples of electrical apparatus for the operation and control of signals, photographs of various installations, and a signal designed for use in the tunnels of the Pennsylvania Railroad under the Hudson River to New York City shown in position in a full-size model of one of the tunnel tubes. The company's most important exhibit at St. Louis, however, is in installations in actual service, including the Westinghouse electro-pneumatic interlocking system at the big union station, which controls all of the passenger yard movements, and is much the largest interlocking apparatus ever built.

A brief guide pamphlet to the Westinghouse exhibits may be secured at the headquarters and exhibits office, in the form of a neat folder which includes maps of St. Louis and the Exposition, and a list of typical Westinghouse installations in St. Louis. Red lines on the St. Louis map show street railways using Westinghouse apparatus. In the city of St. Louis to carry the visitor to the Fair grounds, are 1,000 street cars equipped with Westinghouse air brakes, driven by Westinghouse motors, and operated from stations in which are installed Westinghouse generators with a total capacity of 20,000 hp.

A Two-Belt Conveyor System.

We do not know whether any figures exist showing how much material is now conveyed by belt, motor-driven or otherwise, but in the aggregate the quantities must be enormous, and they would probably keep a fine steam railroad very busy. This field of work is inviting to inventive genius, and it has seen some remarkable improvements and developments. We now illustrate and describe a system that has just been introduced by which a great advance in the art is said to have been made. We refer to the two-belt conveyor system designed by the Ridgway Belt Conveying Company, of New York, in which an interior troughing and supporting belt runs over its individual head and tail pulleys, having separate take-ups, and is entirely independent of the conveying belt proper. The conveying belt is threaded over its head and tail pulleys in the usual manner, and has its separate take-up, so that the two belts, although moving together in the same direction at the same speed, are entirely separate and distinct. This enables the conveying belt to be lifted off the supporting belt and out of the troughing blocks and passed through either a stationary dumper or a moving tripper.

The conveying belt has no work put upon it other than that required to drive the lower carriers and its own head and tail pulleys, all the carriers on the upper line, which comprise two-thirds of the total number used, being revolved by the inner supporting belt.

FIG. 1.—CARRIERS USED IN TWO-BELT CONVEYOR.

The strains, therefore, are divided, the belt revolving two-thirds of the moving parts not being subject to the wear and tear of carrying the load, and the belt carrying the load being relieved of the strains and wear and tear of revolving the greater part of the moving parts of the machine. This produces a divided labor in wear and tear which enables both belts combined only to represent in strength what would be required of one belt in any one-belt system.

The interior belt is driven by a roller or block chain sprocket drive from the main driving shaft, and with the two belts in tension just sufficient to prevent slip on their driving pulleys; both belts move at exactly the same speed in the same direction, and there is no rub

FIG. 2.—INTERIOR TROUGHING AND CARRYING BELT.

of the conveying belt on the troughing blocks. At the points where the conveying belt meets the interior supporting belt, to prevent the rub and wear caused by the troughing blocks moving in a larger radius (the conveying belt being at the same height as the center of the supporting belt) a pair of concentrating rolls lifts the edge of the belt and drops it into the troughing blocks. The same method is used where the conveying belt leaves the troughing blocks at the opposite end.

Fig. 1 shows the carriers used in the two-belt system. They are straight rollers fastened to steel shafts revolving in babbitted boxes, the boxes being ball and socket, ring-oiling, felt-washered and dust-proof. In the two-belt system the conveying belt proper lies in a natural position, a true segment of a circle, with the strains distributed over its whole width uniformly. This increases the life of the belt from 75 per cent. to 100 per cent. over any type of pulley troughing belt. In Fig. 2 is seen the interior troughing and carrying belt with its troughing blocks attached. This interior belt, by a compensating drive, is driven at the same speed as the upper carrying belt, and the two move together through their entire travel on both the upper and lower sides. The conveyor belt proper for the two-belt system is a machine-made belt with a protective cover of average good material. The special belts, which are made to conform to the hard conditions of continuous flexing, are hand-made belts, and to give satisfactory service must be made of the highest grade of material to stand the wear and tear of angular bending.

The inner or troughing belt carries the outer or conveying belt through the upper line of working travel and the outer belt carries the inner belt on its return and through its travel in the lower line. The ability to use straight rollers, all strains being compression strains and not bending or breaking strains, enables the use of the lightest castings that can be machined and finished. This reduces the weight, cost and power required. Only a clean belt comes in contact with the upper carriers, which comprise two-thirds of the total number used. When the conveying belt proper, the only one necessary to be renewed, gives out, the cost of its renewal is stated to be approximately one-half in the two-belt system of what similar material would cost in any type of single belt conveyor. This system has, we are informed, already been put into successful use. Its application to light, power and railway plants is obvious.

A New Three-Point Auto-Starter.

The necessity for gradually applying to a motor the full line voltage of the circuit to which it is connected, in order that the starting torque may be developed by degrees and the starting current reduced, has given rise to a number of appliances suited to the different kinds of service and especially adapted to the motors with which they are to be used. One of such devices, known as the Westinghouse oil-immersed auto-starter, designed for use with Westinghouse type C induction motors, is shown in the accompanying illustration. It is used for motors of 5 to 50 hp; smaller motors of this type being started by closing the circuit with an ordinary switch, and starting

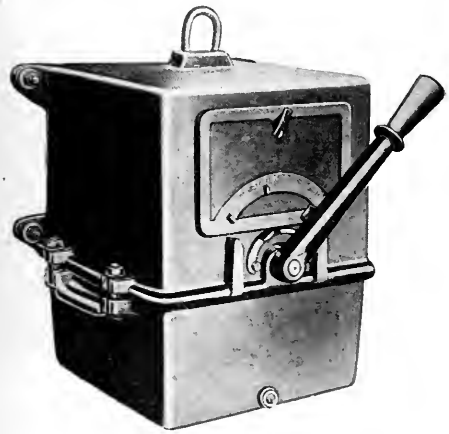

FIG. 1.—AUTO-STARTER.

controllers of another type being used for motors larger than 50 hp.

In effect, the auto-starter described consists of an oil-submerged drum switch used in connection with a pair of auto-transformers which have loops so arranged that a choice of two of several starting voltages is given. It thus combines the functions of a line switch in opening and closing the circuit with those of a controller or starting rheostat with two reduced starting voltages.

The switch, which is of the horizontal drum type, is placed in the oil tank with all live parts submerged, the handle and drum being so connected by gearing that the handle shaft is brought out above the level of the oil. In the style used with 5 to 15-hp motors, the switch is a simple drum on which the fingers bear directly, but in the 20 to 50-hp sizes, which carry larger currents, blades on the drums slide through jaws, giving superior contact. The drum contacts and contact fingers can be easily renewed, and if desired the entire drum can be detached. The absence of flexible leads is of advantage here, as it facilitates the removal of the drum and insures durability.

The drum is so arranged that the movement of the handle is progressive, passing in succession from the off position through the two starting notches to the running position. There is no possibility of moving the handle directly to the running position without first applying the starting voltages, as is frequently done by mistake when

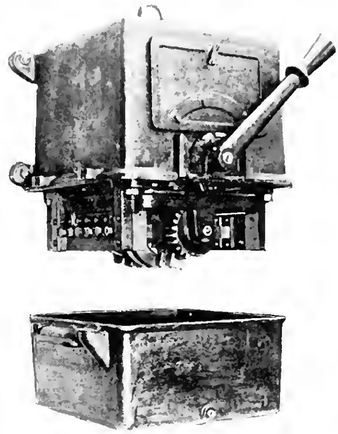

FIG. 2.—AUTO-STARTER.

the off position is placed between the starting and running positions and the handle is thrown first in one direction and then in the other. Nor is the operator so liable to leave the handle in a starting position and ruin the auto-starter by overheating the transformer. The handle is usually placed as shown, but if desired it can be reversed, so that the hand moves below the shaft.

The connections between the drum switch and the auto-transformers are arranged to give the best starting voltages and are adjustable, to suit the conditions of service. Each of the transformers has five taps, giving respectively 30, 40, 50, 60 and 85 per cent. of the full line voltage, and by changing the connections between the transformers, the starting voltage can be changed to give the torque desired. When the handle is in the running position connection is made directly between the motor and the line, the transformer being cut out. When the handle is in the off position both the transformer and motor leads are disconnected, the only live parts being the leads from the generator, a fact of distinct advantage when it is desired to change the transformer connections.

Changing the connections is also facilitated by bringing the transformer taps to the front of the case, where they can be readily reached by removing the hand-hole cover shown in the illustration.

It will be noted that especial attention has been paid throughout to convenience and adaptability to different conditions. In addition to the features mentioned, there are a number of others in which the convenience to the user has been consulted. Access to the drum is facilitated by slotting the lugs through which the bolts pass, so that when the nuts are loosened the bolts can be withdrawn sidewise and the tank lowered. The proper oil level is distinctly marked and drainage and filling tubes are conveniently located. The tank is tightly fitted to the upper portion of the case, and by providing the main hole cover with an air-tight gasket the interior can be protected against acid fumes or dangerous gases. This feature, together with the submersion of all live parts in oil, makes it possible to use the auto-starter where there are inflammable gases or combustible floating particles in the air. As a precautionary measure, the handle is locked in each of the four positions, being released by a pressure upon a button on the end of the handle, this provision preventing a too sudden starting of the motor. The fact that the auto-starter may be placed at any distance from the motor is also an advantage, when motors are suspended from ceilings or placed in other convenient locations.

Thermometer-Thermostat.

The Bristol Company, of Waterbury, Conn., is placing a new instrument upon the market to which has been given the compound name above, since it is a combination thermometer and thermostat. The instrument will give correct indications of the temperature of the atmosphere, gases or liquids at all times, and also serve as a thermostat to make electric connection at any predetermined limits of temperature for the purpose of operating controlling apparatus, alarms and the like.

Fig. 1 shows an external view of the instrument, which is provided with a six-in. scale graduated in degrees Fahrenheit. The construction and capabilities of this instrument will be best understood by referring to the interior view, Fig. 2, in which *A* is an arm

FIG. 1.—THERMOMETER-THERMOSTAT.

pivoted at lower portion of the case, terminating in a point resting on the arc of the graduated scale, and is held by friction at whatever point it may happen to be set. Two adjustable contact pieces, *B* and *C*, are carried by this arm. These contact pieces are capable of adjustment by means of a screw, *D*, which is threaded so as to cause the contact pieces *B* and *C* to approach or recede at equal rates and distance from the center line of the arm, *A*, upon which they are supported. They are also connected to binding posts, as shown, which are used for making outside connections. These binding posts are located within the case to avoid any possibility of the wires or connections being disturbed without detection. Three holes with insulating eyelets are provided in the lower portion of the case, as shown, for the insertion of connecting wires. The high and low contacts can be placed on a single or on independent circuits. The arm, *E*, moving over the graduated scale, indicates the changes of

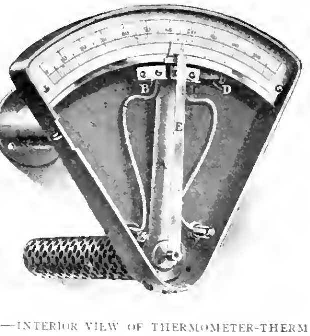

FIG. 2.—INTERIOR VIEW OF THERMOMETER-THERMOSTAT.

temperature where the instrument is located. This arm is operated by one of Bristol's recording thermometer tubes placed in the perforated protecting projection extending from the back of the case, as shown in the illustration. On the back of the indicating pointer, *E*, there is a raised portion which makes electric connection with the contact pieces.

A novel feature of the instrument is that the temperature indicating arm *E* is not restrained by the thermometer-thermostatic contacts. Thus it will be seen that the controlling effect of the thermostat is perfectly adjustable as to position on the scale of the thermometer, and also as to high and low limits of operation, without in any way interfering with the correct indications of the thermometer in case the temperature does not remain, or is not controlled, within the limits for which contact pieces may be set.

The instrument may be readily applied to liquids, as for instance to indicate the temperature and set into operation controlling apparatus for the brine in a refrigerating system or tank.

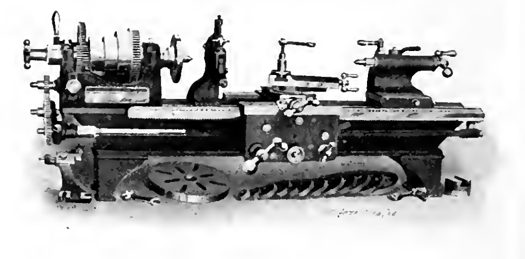
For temperatures above the atmosphere, as that occurring in ovens, kilns, closed spaces, or of liquids in pipes under pressure, a small bulb is located within the closed space or pipe. This bulb is connected with the thermometer-thermostat by a capillary tube filled with alcohol. The temperature at the bulb is communicated to the instrument, which may be located at any convenient point for observation. The electric wires connecting with the adjustable thermostatic contacts may be carried to any point where the controlling apparatus may be located or where it is desired that an alarm shall be given.

New Screw-Cutting Bench Lathe.

There is said to be a growing demand for an accurate and reliable bench lathe than can be bought at a moderate price and at the same time is a complete screw-cutting engine lathe, suitable for laboratory, electrical, optical and experimental work; tool, model scientific instrument making, etc.—in short, for profitable use in all lines of fine, accurate manufacturing and precision service. The "Star Special" screw-cutting bench lathe shown by the accompanying half-tone has been built to supply this demand. The head stock has a large hollow spindle, made from a crucible steel forging, with draw-in chuck for split collets up to ½ in. capacity, and phosphor-bronze boxes with improved end-thrust ball bearings. The cone pulley has three steps for wide belt and with strong back gears gives six changes of speed. A push pin on the head gear allows the cone to be instantly locked or unlocked without using a wrench. The tail stock is the curved or cut-under pattern, which allows the compound rest to swing around parallel with the ways and over the base of the tail stock with room to operate the feed screw handle. The spindle has an improved locking device, and the tail stock is provided with side adjusting screws for turning tapers. There is a long bearing on the bed and it is locked in such a manner as to render it firm and rigid.

The carriage has a long bearing on the ways and is gibbed to the bed both front and rear. A cam-locking device locks the carriage to the bed when using the cross feed. The cross feed screw has a graduated collar which reads in thousandths of an inch and can be set at zero in any position. Plain and compound rests are regularly furnished and easily interchanged. The base is graduated 180° and renders the compound rest capable of fine adjustment. The tool post has a patented collar and shoe which exclude all dirt and chips and admit of quick, easy and secure adjustment of the tool.

The automatic cross and longitudinal feeds are actuated by a



SCREW-CUTTING BENCH LATHE.

phosphor-bronze worm on the lead screw, receiving its power from the head spindle through spur gears. The lead screw is splined and simply acts as a feed rod, hence the only wear on the threads is in screw-cutting. The automatic feeds are almost indispensable for a large variety of work, as they secure more accurate and smoother surfaces. The range of feeds is very large. The range for screw-cutting is extra large, cutting all standard threads, right or left (including 11½ in. and 27 in.), from 3 to 64 without compounding the gears and nearly all threads by compounding. Patented spring nuts are used in connection with split washers to hold the change gears in place. They are easy and convenient to operate and allow quick shifts of the change gears.

The bed is 46 in. long, broad, deep, thoroughly well braced and accurately proportioned throughout. The rated swing is 9 in., but it has an actual swing of 10⅓ in. over bed and 24 in. between centers. The countershaft has friction clutch pulleys easy to operate, strong and durable, and self-aligning and self-oiling shaft bearings. The pulleys and friction bands are provided with self-closing oil cups.

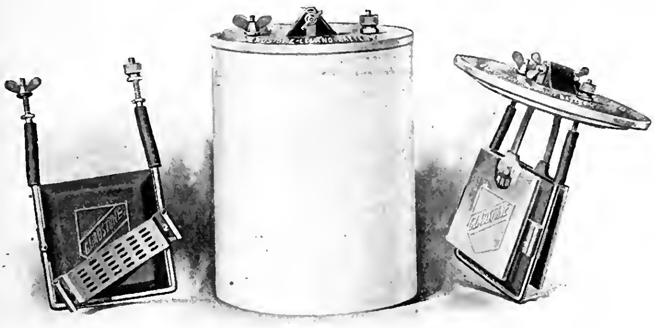
The "Star Special" screw-cutting bench lathe is made by the Seneca Falls Manufacturing Company, Seneca Falls, N. Y., makers of the well-known foot and power "Star" lathes.

The Gladstone-Lalande Primary Battery.

The battery shown in the accompanying illustration is an improvement on the type of battery invented by De Lalande & Chaperon, of which there are several modifications on the market at the present time. In the Gladstone-Lalande battery the negative electrode is composed of a plate of agglomerated oxide of copper, having its surfaces reduced to the metallic state. This copper oxide plate is carried in a supporting hanger, made of copper rod formed into a U-shaped frame, the two free ends of which are threaded to receive clamping nuts, by which it is fastened to the porcelain cover of the battery. This supporting hanger is provided with two perforated flat spring copper clamps, attached to the opposite sides of the hanger. One of these spring clamps is riveted at each end to the hanger, and the other is detachable, having slotted eyelet holes at each end which fit over the two rivet heads on the sides of the hanger; the clamp is locked in position by being pulled slightly in a downward direction. The copper oxide plate is so placed in the hanger that one of its flat surfaces bears against the fixed spring clamp. The detachable spring clamp is then locked to the hanger, as described above, so that it bears against the other flat surface of the oxide plate, which is held firmly between the two spring clamps.

The advantages possessed by this form of construction are that when the battery needs to be recharged the exhausted oxide of copper plate can be removed from the hanger and a new one substituted with the least possible loss of time, and without soiling the fingers. The wide surfaces of contact presented by the perforated spring clamps render it unnecessary for any cleaning or sandpapering of these parts when recharging the battery.

The positive electrode consists in all cases of two flat plates, composed of an alloy of zinc and mercury, which are suspended from the cover. In some models these flat zinc plates are cast on an inverted U-shaped hanger, having a threaded extension which passes through a hole in the cover, to which it is clamped by a suitable nut. In other models (as shown in the illustration) the two zinc plates



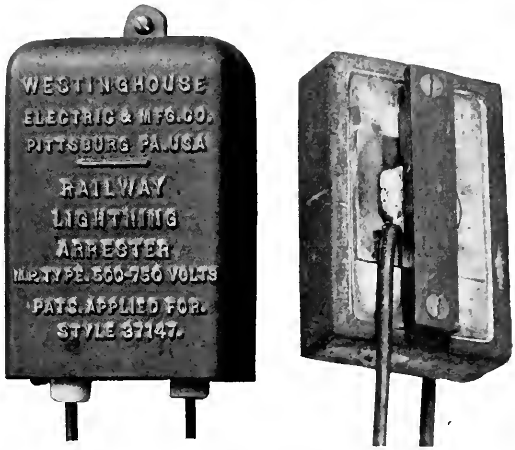
PRIMARY BATTERY.

are cast on separate stems, having a hole at the upper extremity which allows them to be bolted to the projecting knob on the top of the cover, which is provided with a horizontal hole to receive a threaded bolt for this purpose.

The electrolyte in all cases is a 20 per cent. solution of pure caustic soda, and a layer of pure mineral oil is poured on the top of solution to prevent evaporation and creeping. These batteries are manufactured by the Battery Supplies Company, Avon Avenue and Jelliff Avenue, Newark, N. J., the proprietor of which, Mr. J. W. Gladstone, is the inventor.

Multipath Lightning Arrester.

During his extended investigations of static phenomena and the protection of apparatus from lightning discharges, it became evident to Mr. P. H. Thomas that to successfully protect apparatus operated on low-voltage circuits, such for example as railway motors and generators, it would be necessary to produce an arrester which would offer a much easier and more open discharge path to earth than could be found in any arrester previously devised. To protect the arrester from damage, due to the line voltage holding over, was also an essential requirement. As the result of experiments carried



LIGHTNING ARRESTER.

on continuously for several years, both in the laboratory and under actual service conditions, the Westinghouse Electric & Manufacturing Company has placed on the market a new type of lightning arrester, devised along the lines of two general principles, as follows:

1. There is a minimum voltage, below which an arc cannot be maintained across an air-gap, no matter how small that gap may be.
2. Under proper conditions a static discharge will distribute itself over a great number of parallel paths, so that the amount passing over any one path will be very small, producing practically no heating or disintegrating effect. From this second principle the arrester takes its name, multipath (M.P.).

The arrester consists essentially of a specially prepared block of carbon, in which the area offered for discharges is very great as compared to the length of path through which the discharges pass. In this block there are a great number of separate conducting paths, and the discharge passing through the block divides and takes simultaneously many different ones. Each of these paths is broken up by a large number of minute air-gaps, so that the voltage across each gap is very small and the line voltage cannot maintain an arc across them. Thus the arrester is non-arcing, since the line current does not follow the static discharge.

In series with the carbon is a small air-gap rigidly maintained between two metal surfaces. This air-gap keeps the arrester insulated from the line, except at the instant of a discharge. The active parts of the arrester are enclosed in a cast-iron box which is filled with a water-proof compound.

The arrester is weather-proof and fire-proof. It may be used indoors or outdoors and may be located in practically any position desired. Its weight is from ⅓ to ½ that of any other arrester on the market, it is small and compact and has absolutely no moving parts to stick and get out of order. Some of the advantages claimed for the new type of arrester are as follows:

1. Great protective power (low resistance to static discharges). 2. Non-arcing. 3. No moving parts. 4. Fire-proof construction. 5. Light weight. 6. Neat appearance and ease of installation. 7. Simplicity and compactness.

Of the illustrations, the one on the left hand shows the lightning arrester complete, and that on the right shows the interior of it.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—The stock market was exceedingly dull and lifeless. The public is doing nothing, and the operations by professional traders are conducted on a restricted scale. The uncertainty as to the crop situation and the coming political campaign are the supposed principal causes of the lack of interest and inactivity. The decreased railroad earnings did not seem to affect perceptibly the standard railroad stocks, although some little pressure developed in some of the minor railroad specialties. Steel issues were also under some pressure owing to the adverse accounts of the iron industry, although some remarkable prophecies are to be noted as to the enormous business to be done in 1905-6. Preferred declined somewhat, but easily recovered at the end of the week., Brooklyn Rapid Transit was sensitive to further talk regarding increased traffic and earnings. There was a fairly brisk trade in this stock, the sales for the week aggregating 27,670 shares, the closing price being 47⅛, a net gain of ⅜ point. Metropolitan Street Railway closed at 110, the sales amounting to 5,800 shares. General Electric was quiet and weak, only 600 shares having changed hands, at prices ranging between 155 and 156, the closing price being 155 and a net loss of 1 point. Westinghouse closed at 156⅛, and thus gained ⅛ point net. In the telegraph group Bell Telephone lost 1⅛ points, closing at 125¼; Western Union closed at 86¼, this being a loss of ¾, and American Telegraph and Cable gained ¾, closing at 88. There were no features in the curb market, which was quiet. Following are the closing quotations of June 7:

BELL TELEPHONE AND CENSUS.—The recently published census figures on the telephone industry have created much comment in telephone circles in Boston, as they constitute practically the first intelligent effort to secure authentic statistical information regarding this important industry. An official of the American Telephone and Telegraph Company is quoted as saying: "The Government deserves much credit for the figures prepared by the census bureau regarding the telephone. While they were not strictly accurate in all particulars, the figures were as nearly correct as could be secured. The census figures showing 5,000,000,000 telephone 'talks' during 1902 must be accepted with a grain of salt. While the Bell system of recording such figures is as nearly perfect as human ingenuity can make it, our records are likely to be 3 per cent. to 5 per cent. out of the way. We figure that the Bell 'talks' during 1902 were 3,000,000,000, which, according to the census figures, would leave over 2,000,000,000 'talks' for the independents. These latter figures are too large. With the Bell telephones outstanding numbering 1,575,160 (in 1902), there were left for the independents about 750,000. It is absurd to credit the independents with two-thirds as many 'talks' as the Bell companies when we had twice as many telephones outstanding. The statement that the independent companies now have a larger number of telephones outstanding than the Bell companies is incorrect. I do not believe the ratio to-day is more in favor of the independents than it was in 1902, and I have reason to believe that the percentage is steadily increasing in favor of the Bell companies."

NEW ENGLAND TELEPHONE.—The annual report of the New England Telephone Company for last year, already noted in this column, showed share earnings of $1,415,139, equal to 6.5 per cent. on the $21,616,700 capital stock outstanding at the close of the year. As compared with 1903, gross earnings increased $668,255, or 11 per cent.; operating expenses increased $421,884, or 8½ per cent.; and net earnings increased $246,370, or 21 per cent. The percentage of operating expenses to gross earnings was as follows: Gross earnings $6,692,864; operating expenses, $5,277,295; per cent. of expenses to gross earnings, 78.7 per cent. Operating expenses included $288,547 paid in royalties and $208,348 for interest on the funded debt, the former absorbing 4.3 per cent. of gross earnings, and the latter 3.1 per cent.; a total for the two items of 7.4 per cent. It is evident, therefore, that the remaining items of operating expenses absorbed 71.3 per cent. of the gross earnings. The proportion of maintenance expenses to gross earnings is shown as follows: Gross earnings, $6,692,846; maintenance, $2,156,217; per cent. of maintenance to gross earnings, $32.2 per cent. This is a little higher than the average appropriation for maintenance by the Bell companies, which, according to President Fish, is about 30 per cent. of gross.

STREET RAILWAY GROSS EARNINGS.—The *Street Railway Journal* contains a summary of the gross earnings of 310 street railway companies of the United States for 1903, as shown by the figures in its annual valuable "Red Book" issued by the McGraw Publishing Company. The gross receipts of 42 companies having gross receipts of over $1,000,000 each amounted to $169,394,001, against $158,165,809 in 1902; 26 companies having gross receipts between $1,000,000 and $500,000 aggregated $18,019,575, against $16,279,419 in 1902; 100 companies with gross receipts between $500,000 and $100,000 totaled $22,875,139, against $19,638,636 in 1902; 91 companies with receipts between $100,000 and $50,000 amounted to $6,428,053, against $5,873,042 in 1902, and 51 companies with receipts between $50,000 and $25,000 aggregated $1,871,719, against $1,636,423 in 1902. The number of companies in the highest class, that is, those reporting receipts of over $1,000,000, has increased from 38 to 42, and all of these companies record an increase in gross receipts with one exception, where the decrease is due to local causes. The general average increase for 1903 over 1902 by the 310 companies compared is 8.5 per cent.

MEXICAN TROLLEY REPORT.—The report of the Mexico Electric Tramways, Ltd., for 1903 states that the result of the company's operations for the year, after charging interest on the debentures of the "Compania de Ferrocarriles del Distrito Federal de Mexico," and after payment of the 3½ per cent. guaranteed on the share capital of that company, shows a net profit of $135,785. The interest received on the debentures of the "Compania de Ferrocarriles del Distrito Federal de Mexico" and the dividend declared by the "Compania de Ferrocarriles del Distrito Federal de Mexico" on its share capital are then added, and after charging expenses and obligations, etc., a net balance is shown to the credit of profit and loss account of $77,725, which added to the balance brought forward gives the sum of $168,640. Out of this sum the usual dividend of 6 per cent. has been paid on the preference shares, amounting to $150,000, leaving a balance of $18,640 to be carried forward. The increase in the rates of exchange has resulted in a credit of $12,980, which has been placed to exchange suspense account.

INTERNATIONAL NICKEL.—Mr. Charles M. Schwab and his brother, Mr. Joseph H. Schwab, have sold their holdings in the International Nickel Company, according to information in Wall Street. The Schwab brothers were among the largest holders of the securities of the company, and were believed to be practically in control. It is understood that they sold their holdings to a syndicate and that their getting out of the company is only another proof of the desire of Mr. Schwab to reduce his outstanding interests in various concerns. The International Nickel Company was organized in 1902 with a capital stock of $12,000,000 preferred and $12,000,000 common stock. The funded debt of the company was $10,000,000. The company was a consolidation of a number of American and foreign nickel manufacturers, and it was claimed that it practically controlled the nickel output of the world. The president of the company is Ambrose Monell, formerly one of the right-hand men of Mr. Schwab in the Carnegie Steel Company.

DIVIDENDS.—The directors of the Massachusetts Electric Companies have declared the regular semi-annual dividend of 2 per cent. on the preferred stock. The Western Union executive committee has recommended the payment of the regular quarterly dividend of 1¼ per cent. A dividend of 1½ per cent. has been declared on Philadelphia

Union Traction stock, payable July 1. A dividend of $5 a share has been declared on West Philadelphia Passenger stock, payable July 1. A dividend of $4.75 has been declared on Philadelphia Union Passenger stock, payable July 1.

INCREASE OF STROMBERG-CARLSON CAPITAL.—The Stromberg-Carlson Telephone Manufacturing Company has decided to increase its capital stock from $4,500,000 to $6,000,000. It is stated that the Chicago factory will be closed and that all the manufacturing will be done at the company's factory in Rochester, N. Y. The common stock will be increased to 45,000 shares.

Commercial Intelligence.

THE WEEK IN TRADE.—The general situation is quiet and dull. The crop situation is still irregular, reports of improvement coming from some sections, while from others complaints are made. The volume of wholesale and retail business during May, *Bradstreet's* says, was disappointing, confirmation of this being found in decreases in bank clearings and in railroad earnings from a year ago, while failures were more numerous, though less costly than in recent months, but showing increases as compared with last year. There is, however, an underlying confidence in future trade, as is indicated by better inquiry for fall goods. Collections partake of trade irregularity, but are still fair. Among the industries iron and steel and bituminous coal are particularly depressed. Many furnaces are going out of blast, and curtailment continues. Finished products are generally quiet. Export business is expanding, the April shipments being double those of the same month last year. The lake tie-up is still unsettled. This affects shipments and general industry from Buffalo to Duluth. The market for copper was easy and ⅛c. lower at New York. Quotations are 12¾ @ 13c. for Lake, 12⅝ @ 12⅞c. for electrolytic, 12⅜ @ 12½c. for casting stock. The London copper market was lower. According to *Bradstreet's* statistics, there were 194 business failures during the week ending June 2d, as against 184 the previous week, and 157 the corresponding week last year.

ENGINE AND BOAT BUILDERS' ASSOCIATION.—The National Association of Engine and Boat Manufacturers has been formally organized this week in New York City. The membership roll was signed by forty-four of the leading manufacturers in these lines from all parts of the country. The charter of the association, under the laws of the State of New York, was received, and the constitution and by-laws were adopted. H. A. Lozier, of the Lozier Motor Company, presided, and E. W. Graef acted as secretary. It was decided to postpone the election of officers and an executive committee until the next meeting, which will be held at the Manhattan Hotel on June 27th. In the meantime Mr. Graef will communicate with the members and ask all who cannot attend to signify their choice for these offices. The objects of the association are in part as follows: To get special freight rates; to establish a bureau of information; to make special arrangements in regard to and to participate in the profits of shows, to protect its members against adverse legislation and questionable advertising schemes; to bring forward the new and improved methods in construction, and to take such action as will be in the interests of its members as regards alcohol as fuel. The membership of the association is as follows: The Lozier Motor Company, the Standard Machine Construction Company, the Bridgeport Motor Company, the Gas Engine and Power Company, the American Iron Works Company, the Buffalo Gas Machine Company, the Charles A. Strehlinger Company, the Toquet Motor Company, Panhard & Levassor, the Matthews Boat Company, the Isham Company, Fred Hock, the Delaware River Motor Company, Pilmer Brothers, the Standard Boat Company, the E. Gerry Emmons Corporation, Norwood Brothers & Co., the Eagle Bicycle Company, the Cushman Motor Company, the Wolverine Motor Works, Lacey Brothers, the Chase Pulley Company, A. Barrett's Sons, the Pearson Boat Construction Company, Termadt & Monahan, the Truscott Motor Company, the Pierce Engine Company, the White Craft and Power Company, Charles Durkee & Co., the Smalley Motor Company, the Miamus Motor Company, the Outing Boat Company, the Remy Electric Company, William Roche, the Stanford Motor Company, E. W. Graef, the Smith & Mabley Manufacturing Company, the Milton's Point Shipyards, T. S. & A. D. Negus, the Electric Launch Company, A. Paterson, the Motor Boat, Motoring and Boating, and the Automobile.

EQUIPMENT FOR BARBOUR FLAX MILLS.—The Barbour Flax Spinning Company, of Paterson, N. J., has awarded the important contract for the electrical equipment of its new shops to the Crocker-Wheeler Company. The equipment will comprise a 600-kw engine type, 110 r.p.m., 250 volts, direct-current generator, which will be direct connected to a 1,000-hp Corliss engine. There will be 25 standard motors, ranging in size from 5 hp to 25 hp each. Eighteen will have a capacity of 25 hp; two will be 15 hp; three will be 10 hp and two will be of 5 hp each—520 hp in all. The Crocker-Wheeler people have also secured the order for the switchboard.

MOTOR EQUIPMENT FOR LONG ISLAND MARBLE PLANT.—An extensive motor equipment has just been ordered for installation in the plant at Ravenswood, L. I., operated by the Traitel Marble Company. There will be 24 Crocker-Wheeler motors, practically all of which will be individual drive. The equipment will aggregate 275 hp in capacity. The motors will range from 2 hp to 35 hp. The machines will include standard, fully enclosed and semi-enclosed types. There will also be four grinders, built by the Bridgeport (Conn.) Safety Emery Wheel Company, Inc., which will be driven by Crocker-Wheeler motors.

EQUIPMENT FOR MEXICAN SUGAR PLANT.—The San Juan Sugar Corporation, of which Mr. E. V. Weems, of Winchester, W. Va., is president, will shortly let contracts through Mr. George T. Anderton, consulting engineer, 120 Liberty street, for a quantity of electric equipment to be used for lighting and largely operating a 1,000-ton sugar plant to be built on the Miller Plantation Company's property, State of Vera Cruz, Mexico. The contract for the boilers, 1,200 hp in four units, has already been awarded to the Sterling Co., 114 Liberty street, New York.

THREE THOUSAND HP NEW ZEALAND HYDRAULIC PLANT.—The Waipari Electric Power Company is to construct a plant on the Waipari River near Dunedin for generating current to operate the municipal electric traction system of that New Zealand city, whose lines are now worked from a steam plant. The initial capacity of the Waipari plant will be about 3,000 hp. The Pelton Water Wheel Company, 143 Liberty street, has been allotted the contract for the water wheels. The General Electric Company will build the generators.

EQUIPMENT FOR ABRAHAM & STRAUSS.—The contracts for the additional lighting equipment to be installed in the Abraham & Strauss store, Brooklyn, have just been awarded through Mr. C. O Mailloux, consulting engineer. There will be a 400-kw, 115-volt generator, which will be built by the General Electric Company and direct connected to a tandem non-condensing compound Corliss engine of 600 hp capacity. The engine contract went to the C. & G. Cooper Co., Havemeyer Building, New York City.

EQUIPMENT FOR NEW YORK BUTCHERS' DRESSED MEAT PLANT.—Contracts are about to be let for several motors, varying in capacity from 1 hp to 40 hp, wiring, coal handling machinery, etc., for installation in the New York Butchers' Dressed Meat Company's plant, New York City. The generators—two 400 kw and one 200 kw—will be built by the General Electric Company. The engines will be built by the Fitchburg (Mass.) Engine Company. Hogan & Slattery are letting the contracts.

MOTORS, ETC., FOR NEW GORHAM BUILDING.—It has been decided that the electric current to be used in the new Gorham Manufacturing Company Building, Thirty-sixth street and Sixth avenue, New York, will be taken from the Edison mains. About 200 hp of motors for ventilating apparatus will, however, be ordered very shortly through Mr. C. O. Mailloux, consulting engineer. There will be 2,400 16-cp incandescent lamps and a number of arcs used to light the premises.

TELPHERAGE FOR JAPAN.—The Imperial Government of Japan has just ordered from the United Telpherage Company, of 20 Broad Street, New York City, a second telpherage plant. The company some time ago installed one complete plant, and the Japanese were so well pleased with it that the second plant was ordered by cable. Shipment is to be made of complete plant in thirty days, which order the Telpherage Company with its increased facilities can promptly fill.

EQUIPMENT FOR PROCTOR & GAMBLE PLANTS.—A considerable quantity of electrical equipment is to be installed in the new soap making plant of Proctor & Gamble, at Kansas City. Robert W. Woodward, the mechanical superintendent of the company's chief plants at Cincinnati, Ohio, will let the contracts for the Kansas City equipment. The installation of further equipment in the Cincinnati works is also contemplated.

THE AMERICAN ELECTRIC TELEPHONE COMPANY of Chicago reports that its exchanges recently installed at Hot Springs, Ark., and Fort Worth, Tex., are operating very satisfactorily. Both exchanges are equipped with four party-line selective apparatus throughout. The adoption of the American Company's four-party selective system is held largely responsible for the immense success of the new company.

FANS FOR MONTEREY.—The Wesco Electrical Supply Co., of St. Louis, Mo., has secured a large contract for fans to be shipped to Monterey, Mexico.

General News.

THE TELEPHONE.

REDDING, CAL.—The Northern Trinity Telephone Company is to build a telephone line between Delta and Carrville, a distance of 25 miles. Mr. Carr is interested in the company.

EMMET, IDA.—The Rocky Mountain Bell Telephone Company plans the early construction of a line between this city and Roosevelt, in Thunder Mountain. The distance is 160 miles, and on account of the mountainous nature of the country the cost is estimated at about $100,000.

DECATUR, ILL.—The capital of the Macon County Telephone Company has been increased from $20,000 to $75,000.

GOLDEN, ILL.—The German Telephone Company has been incorporated with a capital stock of $5000. The directors are A. Baryell, D. G. Buss and others.

REDDICK, ILL.—The Reddick Mutual Telephone Company has been incorporated with a capital stock of $5000. The directors are James Reilly, I. G. McLane and others.

JOHNSTON CITY, ILL.—The Johnston City Telephone Company has been incorporated with a capital stock of $8000. The directors are C. E. McLintock, W. A. Roberts and others.

HARMONY, IND.—A new telephone exchange is being installed at this place, which will be connected with the Citizens' exchange of Brazil.

FLORA, IND.—The Flora & Bringhurst Co-operative Telephone Company has been incorporated with a capital stock of $13,000. The directors are W. F. Wagener, J. H. Coplin and others.

INDIANAPOLIS, IND.—The Stampers Creek & Orleans Telephone Company, of Orange County, has been incorporated with a capital stock of $200. The directors are B. F. Williams, H. McCoy and others.

INDIANAPOLIS, IND.—The New Telephone Company is preparing to extend its underground conduit system. When this work is completed a large area of the central portion of the city will be occupied by the conduits.

NEWCASTLE, IND.—Improvements calling for an expenditure of $25,000 are to be made by the two telephone companies here—the Central Union and the Independent. Several miles of new cable are to be put in and extensions of lines into the country in different directions are to be made. The extensive work marked out will require all summer to complete. Several of the toll lines are being doubled on account of heavy business.

INDIANAPOLIS, IND.—A peculiar telephone suit has been brought by Ashjian Brothers, a manufacturing firm of this city, against the Indianapolis Telephone company, to recover $5000 damages on account of the company having failed to place their name and number in the latest issue of its directory. Plaintiffs allege that the business of the firm has suffered great loss by the omission, and aside from the damages it is asked that the defendant company be required to issue a new directory.

ELWOOD, IND.—In an exciting race against time between the Central Union Telephone Company and the Delaware & Madison County Company, whereby the first in the field was likely to get the new suburban line from Elwood to Curtisville, the independent company won. The Delaware & Madison County Company had teams employed hauling poles all night and started three gangs of men to work erecting them at daybreak. All the farmers along the line and many of the Curtisville residents will be on the new system.

PORTLAND, IND.—The war between the city authorities and the Central Union Telephone Company has been waged for some time and the bitterness was increased by the city council passing a resolution ordering the arrest of any employe of the company found at work on the streets. The city authorities contend that the company has no franchise. The company disregarded the resolution and put its men to work and they were promptly arrested and charged with obstructing the streets. The city has brought quo warranto proceedings against the company to compel it to show by what right it seeks to plant poles in the streets. The company claims that a franchise was granted it in 1882, but has not produced the instrument.

EVANSVILLE, IND.—The telephone situation grows more interesting every day. The Home Telephone Company, recently organized, has applied to the Board of Public Works for a franchise and agrees to pay the city $4000 annually for 30 years and suggests allowing this money to remain in the hands of the telephone company at 3 per cent. interest, to be applied on the purchase price of the exchange by the city at any five-year period after the first ten years. Otherwise the city has the right to purchase the plant by paying one-half of the price stipulated in cash and the remainder in four annual installments. The company agrees to file a bond of $10,000 to have the plant completed and in operation within one year after granting of the franchise. The company also agrees not to assign to any company now in the field, or that shall be allowed to operate in the city, the franchise or contract granted to it by the city. The charges asked are as follows: Business telephones, $4; residence, $2; party line, $1. After 6000 subscribers are secured the company is given the right to increase the price 25 cents for each additional thousand. Immediately upon information that the Home Telephone Company had applied for a franchise the Citizens Telephone Company sent a communication to the council asking that it grant to the Home Telephone Company the franchise submitted by it, provided only that such conditions be imposed as will secure to the city the establishment of a system under that franchise within a reasonable time and the payment at once to the city of a sum sufficiently large to secure it from loss in case of any failure to establish such plant within such reasonable time. Also that conditions be imposed which will require and secure connection with independent long-distance telephones and that the maximum charges be no higher than those asked by the Citizens Company. The granting of a franchise upon such conditions will be sufficient to warrant the Citizens Company to withdraw its application for a franchise; for, if in good faith any other company offers better terms to the city, the Citizens Company does not care to intervene. The council has taken no action as yet upon the application of the Home Company or the withdrawal of the Citizens Company. The Home Company is composed of wealthy manufacturers, and it will not be surprising if this company does not yet build the new exchange in Evansville.

BONAPARTE, IA.—The Farmers' Connective Telephone Company has been incorporated with $10,000 capital stock.

SOUTH McALESTER, I. T.—Articles of incorporation have been issued to the Goodwater Telephone Company, of Goodwater, Okla. The capital stock of the company is $2000, and the incorporators are W. J. Whitemore, president; B. S. Harris, vice-president; W. H. McBrayer, secretary-treasurer.

CONCORDIA, KAN.—The Farmers' Central Telephone Company has been incorporated with a capital stock of $10,000.

HOME CITY, KAN.—The Home City Farmers' Mutual Telephone Company has been incorporated with a capital stock of $2100.

THIBODEAUX, LA.—The Cumberland Telegraph & Telephone Company is installing a new 400-line multiple board in its exchange here. It is also making other improvements to its system.

TRAVERSE, MINN.—The Farmers' Co-operative Telephone Company has been incorporated with a capital stock of $12,000.

WATERTOWN, MINN.—The Watertown Telephone Company has been incorporated with a capital stock of $25,000. F. A. Barth is president.

WINONA, MINN.—The Farmers' Co-operative Telephone Company has been incorporated with a capital stock of $12,000. The directors of the company are C. L. Nelson, F. E. Briggs and others.

HOPKINS, MISS.—The Rural Telephone Company, of Hopkins, has been chartered with $500 capital. W. N. Bailey and others are stockholders.

YAZOO CITY, MISS.—Both the Mutual and Cumberland telephone exchanges were destroyed by the recent fire at this place.

CLINTON, MO.—The Clinton Mutual Telephone Company has increased its capital stock from $20,000 to $50,000.

ST. LOUIS, MO.—The assessed valuation of the telegraph and telephone companies' properties in St. Louis County has been fixed by the County Court as follows: Bell Telephone Company, 110.33 miles of poles, $6619.80; 511.45 miles of wire, $5114.50, exclusive of incorporated towns, where it was valued at $60 a mile for poles and $10 a mile for wires. American Telegraph & Telephone Company, 42.65 miles of poles at $60 a mile; 314.74 miles of wire at $10 a mile, and 1029 feet of cable, $110. Kinloch Long-Distance Telephone Company, 15 miles of poles at $60 a mile, and 391 miles of wire at $15 per mile. Pacific Mutual Telephone Company 27.55 miles of poles at $60 a mile and 218 miles of wire at $10 per mile.

ODELL, NEB.—The Odell Independent Telephone Company has been incorporated with a capital stock of $10,000.

ARAPAHOE, NEB.—The Arapahoe Independent Telephone Company has been organized in this place by local capitalists. The company has an authorized capital stock of $20,000. The company has recently started business with 64 telephones connected.

NORTH WEARE, N. H.—The Weare Telephone Company has been organized. Frank Simmons and S. B. Herbert are among the directors.

BATAVIA, N. Y.—The village trustees have granted a perpetual franchise to the Bell Telephone Company for the operation of an exchange in this village. The company agrees in return to give the village $250 worth of service annually.

WALDO, OHIO.—The Waldo Bell Telephone Company has been incorporated with a capital stock of $5000. The directors of the company are J. D. Bower, W. F. Groll and others.

GREENVILLE, OHIO.—The Eldorado & West Manchester Telephone Company has been incorporated with a capital stock of $40,000. The directors of the company are W. D. Rush, R. S. Conkling and others.

OTTAWA, OHIO.—The Ottawa Mutual Telephone Company has been incorporated with a capital stock of $1000. The incorporators are C. O. Beardsley, J. H. Purnell, F. E. Smith, E. L. Tupper and George Fritz.

CINCINNATI, OHIO.—The Probate Court has decided that the Queen City Telephone Company is entitled to the use of the streets of Cincinnati for its wires, and prescribes the manner in which the franchise should be exercised. An appeal is to be taken.

BAKER CITY, ORE.—The Snake River Telephone & Telegraph Company will construct a telephone line down the Snake River to the Iron Duke mine and connect with other mining and agricultural systems in that region.

UNIONTOWN, PA.—The telephone line to connect Uniontown with Pittsburg over the lines of the Tri-State and Pittsburg & Allegheny Telephone Companies has been completed. The Tri-State Company has 2000 subscribers in Lafayette County and covers practically the entire county.

SCHULENBERG, TEX.—The Schulenberg Telephone Company has been incorporated with a capital stock of $5000. The directors are W. E. Perlitz, John Schumacher and others.

SEATTLE, WASH.—An organization of all the independent telephone companies in Washington is being proposed by the Independent Telephone Company of this city. This would give them a long distance service and enable them to compete effectively with the Rocky Mountain Bell system.

PRAIRIE DU CHIEN, WIS.—The Star Telephone Company has been incorporated with a capital stock of $14,000. The directors are M. Menges, J. A. Haggerty and others.

ELECTRIC LIGHT AND POWER.

SEWARD, ALASKA.—Albert Higginson, George Bohus, Harry Kennedy and W. E. Catzdanner have secured a franchise for an electric light plant in this place. They will soon start work on a plant of 1700 lights capacity.

CAMDEN, ARK.—The Fensenthal Land & Townsite Company, Camden, proposes constructing water works, an electric light plant and telephone system, but no definite plans have yet been made.

OCEANSIDE, CAL.—Bids are wanted July 5 for a gas and electric light franchise. H. D. Brodie is City Clerk.

EUREKA, CAL.—John M. Vance, president of the Humboldt County Bank, is reported interested in the construction of a power plant and the transmitting of power to this city.

SAN FRANCISCO, CAL.—The Merced Falls Power Company, controlled by the Crocker Estate, has ordered through the Wagner-Bullock Electric Company, a 225-kw polyphase Bullock generator.

IMPERIAL, CAL.—The Holton Power Company, of Imperial, has closed a contract with the Wagner-Bullock Electric Company for an 800-hp Bullock railway generator to operate an electric road.

RIVERSIDE, CAL.—W. D. Woolwine, of Los Angeles, has been appointed receiver for the Riverside Power Company. This action grows out of the foreclosure suit of the Mercantile Trust Company of San Francisco.

ALAMEDA, CAL.—The monthly report of the Municipal Electric Light Department shows expenses for April to have been $22,006 and the earnings $1223. These earnings, it is said, are almost $300 in excess of those of the corresponding period last year.

SAN FRANCISCO, CAL.—The new board of directors of the California Gas & Electric Corporation, organized by re-electing the following officers: E. J. de Sabla, Jr., president; John Martin, first vice-president; F. G. Drum, second vice-president; R. M. Hotaling, treasurer, and C. W. Conlisk, secretary. John A. Britton is manager and G. Baum remains superintendent.

ETNA, CAL.—The Siskiyou Electric Power Company on June 1 took over the electric plant of the Etna Development Company. The Siskiyou Company, which has a capacity of 3500-hp at its plants, located at Fall Creek, and elsewhere, lights Ashland, Ore., Fort Jones and other California towns. A line will be constructed to Salmon River to furnish power for the quartz mills.

SANTA MARIA, CAL.—The Santa Maria Power & Lighting Company has filed articles of incorporation to furnish electric light and power in this city. The capital stock is $50,000, nearly all of which is held by Los Angeles and Pasadena men. The first board of directors is composed of H. T. Duff, W. F. Gibbs, R. H. Pallard and F. C. Armstrong, of Los Angeles, and B. E. Page, of Pasadena.

SAN FRANCISCO, CAL.—The Mt. Lassen Water Power Company, which has been incorporated by Archibald Barnard, L. M. Robbins, A. G. Sheath, M. A. Kenney and A. E. Bennett, has a capital stock of $500,000. The principal place of business is San Francisco. Harry L. Shannon has secured the necessary money to purchase machinery for the water power electric plant, which this company was organized to construct in Shasta County, Cal. It will be in a position to compete with the Northern California Power Company, which transmits to Redding and many other points. The initial installation will include a 1500-hp direct connected 3-phase generator, the water wheel operating under a head of 1500 feet. Water will be taken from Flat Creek, just below Mt. Lassen, and carried six miles to Bear Creek by ditch and flume. Thence a pipe line will supply water to the power house near Bear Creek Falls. The plant is to be in operation Jan. 1, 1905. A second unit will be installed later.

SAN FRANCISCO, CAL.—The North Mountain Power Company has closed contracts through the Wagner-Bullock Electric Company of San Francisco for two 75-kw, 3-phase Bullock generators, arranged for direct connection to Stilwell-Bierce water wheels. A third unit will soon be ordered. The 25-cycle machines will generate 2200-volt current at 500 r.p.m. Transformers for the generating capacity have been ordered in 300-kw units, with one spare bank. There will be several sub-stations. The power station will be built at a point 40 miles west of Redding in Humboldt County, and energy will be transmitted 75 miles to Eureka at 33,000 volts. Current for lights, power and electric railways will be supplied. This plant will be only a beginning and the system will be developed until 25,000-hp or more will be available for transmission to all of the important towns, mines and manufactories of Northwestern California. Early deliveries of machinery will be made and the initial plant installed in time to open for business before Jan. 1, 1905. An available head of 600 feet of water will be utilized. The North Mountain Power Company has a capitalization of $500,000. John M. Vance and Wm. Carson, of Eureka; John L. Koster, F. J. Koster, D. G. Schofield and R. J. Tyson, of San Francisco, are stockholders. J. C. Ralston, chief engineer, has commenced work at both ends of the proposed transmission line. For several years the company has been examining the mountain streams of Humboldt, Mendocino, Trinity, Del Norte and Siskiyou counties. The water rights and ditches of the Compagnie Francaise, doing business in Trinity County, have been purchased and an electric power plant will be installed in that mining district.

CHESHIRE, CONN.—The large transforming station of the Connecticut Railway & Lighting Company in this place is now completed. The main station is at Bull's Bridge, near New Milford, where there is a hydraulic plant. Electrical energy is transmitted to Cheshire at a pressure of 30,000 volts.

SEYMOUR, CONN.—W. H. H. Wooster and George E. Matthies, who control the Seymour Mfg. Company, Seymour, Conn., have bought the property of the Seymour Electric Light Company. Both industries depend upon water privileges one above the other on the Naugatuck River, and the best economy and results can only be obtained by working the plants in harmony.

KEY WEST, FLA.—The Key West Electric Light Company has absorbed the Electric Light & Power Company of this city. For the present both the plants will be operated. New machinery has been ordered and as soon as it is installed the power will be furnished from the Key West Electric Company's plant. The Electric Light & Power Company will continue the manufacture of ice.

MILLEDGEVILLE, GA.—Chas. F. Howe, manager of the Oconee Electric Light & Power Company, states that it is proposed to expend from $500,000 to $750,000 in improvements. The company will do the work itself.

MACON, GA.—An application for a charter for the Piedmont Power Company has been filed. The company proposes to generate power from the water streams of the State; also utilize the Oconee and the Ocmulgee for the generation of electricity for power, lighting and heating plants and for the operation of street cars. The capital is $2,000,000. Robt. L. Park, F. M. Marriot and Wm. A. Carlisle are the incorporators.

QUINCY, ILL.—The Quincy Gas & Electric Company has perfected plans which will require an expenditure of $50,000 for improvements during the coming summer.

MT. VERNON, IND.—The Mt. Vernon Electric Light & Power Company has been incorporated; capital, $5000. Directors: Jesse H. Purdy, Geo. E. Hoffmaister, Harry B. Rhine and others.

INDIANAPOLIS, IND.—The Merchants' Heat & Light Company will improve and enlarge its plant at New Jersey and Pearl Streets this summer. James B. Nelson is general manager.

FORT WAYNE, IND.—It is stated that the Fort Wayne Electric Light & Power Company has been sold to Eastern capitalists at a price a trifle over $500,000. It is further stated that the new owners will consolidate the company with the traction interests of the Fort Wayne & Wabash Valley lines. Mr. Randall Morgan, of Philadelphia, is interested in the deal.

WEST POINT, IA.—The council is securing estimates of cost for an electric light plant.

WILTON JUNCTION, IA.—The proposition to issue $5000 electric light improvement bonds was carried at a recent election.

FT. MADISON, IA.—Samuel Atlee is reported to have purchased the franchises recently granted F. C. Wood for an electric light plant and interurban railway system and for a gas plant.

WICKLIFFE, KY.—R. E. Gannon, of Cairo, has secured the contract for an electric light plant for Wickliffe, at $6042.

HOPKINSVILLE, KY.—The electric light plant owned by the Hopkinsville Gas & Lighting Company was destroyed by fire May 22, entailing a loss of $30,000.

INDIAN ORCHARD, MASS.—An electric light and power plant will be installed in the works of the Massachusetts Fiberloid Company of this place. The plant will have a capacity of 1000-hp, and 1000 incandescent lights will be installed.

MANTON, MICH.—The citizens have voted to issue $8000 electric light and water bonds.

SCHOOLCRAFT, MICH.—The electric light plant at this place was destroyed by fire on May 15.

SAULT STE. MARIE, MICH.—The Sault Edison Company is preparing to construct an electric light plant.

JANESVILLE, MINN.—It was voted May 16 to issue $25,000 bonds for the construction of water works and an electric light plant.

OXFORD, MISS.—The citizens voted May 20 to make improvements to the electric light plant.

HATTIESBURG, MISS.—The City Clerk writes that the matter of constructing an electric light plant, for which $60,000 bonds were to have been issued, has been postponed indefinitely.

LOUISIANA, MO.—The Louisiana Gas & Electric Light Company is contemplating improvements in its plant.

SEDALIA, MO.—A charter has been granted the United Water, Gas & Electric Company, of Sedalia, with a capital of $1,000,000. This concern is a consolidation of the companies formerly doing business in this place.

TEKAMAH, NEB.—The electric light plant at this place was damaged by a tornado on June 2, and the town is in total darkness.

CAMBRIDGE, NEB.—The Cambridge electric light plant, which has been operated under the management of P. B. Cole, has been organized as the Cambridge Electric Light Company with a capital of $10,000. Directors: W. H. Faling, J. H. Rosenfelt, E. C. Rodwell and others.

VIRGINIA CITY, NEV.—The Truckee River General Electric Company will install an addition to its present plant of between 2000 and 3000-hp, and will build a new 35-mile line and a sub-station during the present summer. Surveys are now under way, the plant to be driven by water power.

TRENTON, N. J.—Richard Stockton, of this city, has been named as receiver for the Freehold Electric Light, Heat & Power Company on the complaint of Mr. Charles P. Fitch, of Beverly.

JERSEY CITY, N. J.—The Commonwealth Electric Company has been incorporated with a capital of $100,000, to furnish light, heat and power. Registered office, 15 Exchange Place, Jersey City.

CAMDEN, N. J.—The Lighting Committee has awarded a 5-year contract to the Public Service Corporation Company to furnish arc lights at $109 per year per lamp. There are 524 lamps. The total cost per year will be $57,378.

ROSWELL, N. M.—The Roswell Electric Light & Power Company is extending its system, for which work material has already been ordered.

ADDISON, N. Y.—It is proposed to rebuild the electric light plant recently burned. Address F. W. Wheaton.

GOWANDA, N. Y.—It is said to be the intention of the Gowanda Electric Light Company to rebuild the dam across Cattaraugus Creek and operate its dynamos with water power.

LOCKPORT, N. Y.—It is stated that the Niagara, Lockport & Ontario Power Company will build the canal under the present charter and seek an amendment next year, which will authorize it to sell power to all counties of the State instead of only Erie, Niagara and Orleans.

BUFFALO, N. Y.—The Le Roy Hydraulic Electric Company, the Le Roy Gas & Electric Company and the Le Roy Power Milling Company have been consolidated, the new capital being fixed at $100,000. A number of improvements in the plant are to be made and the business considerably extended.

ALBION, N. Y.—The Albion Electric Light, Power & Gas Company, of Albion, which is also owner of the electrical plants at Waterport, Brockport and Middleport, is reported interested in a deal to develop a large water power at the latter village, approximating in the neighborhood of 25,000 horse-power.

ROCHESTER, N. Y.—The merger certificate of the Rochester Gas & Electric Company and the Municipal Gas & Electric Company has been filed with the Secretary of State. The filing of the papers was made necessary at this time on account of the proposed merging of the Rochester Railway and the gas and electric companies into the new Rochester Railway & Light Company.

ALBANY, N. Y.—The Kings County Lighting Company has been incorporated with a capital stock of $2,000,000 to manufacture and supply gas and electricity in Brooklyn and Queens Boroughs, New York City. The directors are Ashley T. Cole, Charles T. Lark, New York City; William J. Bagnall, Bayonne, N. J.; Alex. Keogh, New Rochelle, and W. R. Fuller, Brooklyn.

LAWNDALE, N. C.—The Lily Mill & Power Company, of Lawndale, is authorized to increase its capital stock from $50,000 to $100,000.

GREENVILLE, N. C.—Bids will be received on June 22 by the Board of Internal Improvements (L. J. Hooten, chairman) for the construction of an electric light plant.

LIDGERWOOD, N. D.—The council is considering the construction of an electric light plant.

WIMBLETON, N. D.—Fred Zollner, of Courtenay, N. D., has purchased the electric light plant here, and will install new machinery.

WEST MILTON, OHIO.—The matter of establishing an electric light plant is under consideration.

DOYLESTOWN, OHIO.—The proposition to issue $10,000 municipal lighting bonds will shortly be submitted to a vote of the people.

FREMONT, OHIO.—It is stated that the Fremont Light & Power Company is to utilize the water in Sandusky River here and erect a large power plant.

SUMPTER, ORE.—The Sanger Gold Mines Company proposes to construct a power plant at the mines, to cost about $100,000. J. K. Ronig, Baker City, is superintendent.

CLEVELAND, OHIO.—Bids will be received July 12 by H. H. Bohning, village clerk, of Newburgh Heights, for furnishing material and lighting the streets in that village.

NEWTON FALLS, OHIO.—The Village Council has awarded a 10-year contract for lighting the village with electricity to E. E. Mandeville, of Philadelphia, Pa. He is to build and equip the plant, and furnish 16 arc lights at $70 per lamp. A twenty-year franchise for commercial lighting and furnishing power also went with the contract.

MECHANICSBURG, PA.—Bids are wanted July 1 for electric lighting the city. Murray H. Spahr is chairman of the Light Committee.

BLOOMSBURG, PA.—The newly incorporated Irondale Electric Light, Heat & Power Company, of Bloomsburg, proposes to supply Bloomsburg, Catawissa, Rupert and Danville with electricity.

PHILADELPHIA, PA.—The Philadelphia Electric Company is said to be about to award contract for two more 7000-hp generator units for the Gray's Ferry plant similar to the General Electric unit now installed.

HANOVER, PA.—A charter has been granted to the Hanover Electric Power & Heating Company of Hanover, with a capital of $50,000, represented by Geo. Gitt, Chas. Delone, Thos. O'Neil and others, to construct a heating system.

MT. PLEASANT, PA.—The Hartigan Electric Light, Heat & Power Company, with John F. Hartigan, J. L. Kalp and others, of Mt. Pleasant, as directors, are about to apply for a charter to supply light, heat and power by electricity in Mt. Pleasant.

PITTSBURG, PA.—The United Electric Company of Wilmerding, which was formed recently, has placed an order with the Westinghouse Machine Company for two 200-hp engines and has contracted with the Westinghouse Electric & Mfg. Company for two 150-kw generators. This equipment is to be installed in its new plant, work upon which is now going forward.

PITTSBURG, PA.—An application has been made for a charter for the Great Tunnel Company, the object of which is to construct tunnels under the cities of Pittsburg and Allegheny for the transportation of freight. The motive power is to be electricity and the system is to be modeled after the one now in use in Chicago. Among those interested in the enterprise are Ralph E. Flinn and J. S. Weller.

YORK, PA.—The York Haven Water & Power Company has filed a mortgage for $1,000,000 in favor of the Land Title & Trust Company of Philadelphia to secure a second mortgage bond issued for that amount. The proceeds will be used for equipment, extensions, etc., as the business of the company demands. The rebuilding of that portion of the plant of the York Haven Power Company which was destroyed by the high water and ice several months ago is nearly completed. The plant will hereafter be better protected from like damage.

BATESBURG, S. C.—It was voted May 24 to issue $20,000 bonds for constructing water works and an electric light plant. J. C. Glover is City Clerk.

BATESBURG, S. C.—The town of Batesburg has voted a sum not to exceed $20,000 for water and light plants and other public improvements. W. H. Timmerman is on the committee having in hand the issuing of the new bonds.

BROWNSVILLE, TEX.—The City Council has granted Judge Jas. B. Wells, of Brownsville, a franchise for water works and an electric light plant. He will also establish an electric light plant at Matamoras, Mex.

SALT LAKE CITY, UTAH.—An expert appointed by the city council to investigate the alleged poor and irregular light service of the Utah Light & Railway Company has submitted a report, stating that the city is receiving all the electrical energy called for in the contract. There has been much criticism of the company's service, and the establishment of a rival power plant is being seriously considered.

BURLINGTON, VT.—It is proposed to construct an electric light plant here to cost $50,000.

WEST POINT, VA.—Bids will be received by the Town Council on June 10 for sale of a franchise to light the town by electricity.

PETERSBURG, VA.—The Finance Committee of the Council is considering the construction of an electric light plant.

HARRISONBURG, VA.—The Council is stated to have decided to install a municipal electric light plant costing about $70,000. The power will be secured from the Shenandoah River.

MOUNDSVILLE, W. VA.—The council has granted a franchise to the Moundsville Electric Company. A 50-year extension was granted, and the company now has the plans for a $25,000 plant ready.

CHARLESTOWN, W. VA.—The authorities of Charlestown have taken steps to annul the franchise of the Kanawha Water & Light Company, on the alleged ground that the company has failed to comply with the terms of its franchise.

WITTENBURG, WIS.—The Central Construction Company, of Oshkosh, Wis., has secured the contract for an electric light plant. The probable cost is $10,000.

BERLIN, WIS.—Bids are wanted July 1 for furnishing and providing, on moonlight schedule, 46 electric arc street lamps for the terms of 5 and 10 years from June 1, 1905, and such additional lamps as the city may require from time to time. Henry Morman is City Clerk.

MILWAUKEE, WIS.—The finance committee of the common council here has voted unanimously to recommend a bond issue of $150,000 for the purpose of establishing a municipal electric lighting plant. This matter has been agitated in Milwaukee for a long time and has been endorsed by all the political parties. Plans and estimates have been made by the city engineer and Jones Island is favorably considered for the location of the plant.

LARAMIE, WYO.—David McCullagh, City Clerk, writes that the city would like to correspond in regard to the construction of an electric light plant. The council is talking of installing a municipal plant.

RAT PORTAGE, ONT.—The town of Rat Portage contemplates building a new power station.

BRANDON, MAN.—A charter has been granted to the Western Light & Power Company, of Brandon, with a capital of $300,000, to install an electric plant on Assiniboine River. J. M. Robinson and John Russell, of Brandon, are among the incorporators.

THE ELECTRIC RAILWAY.

BESSEMER, ALA.—Estimates of the engineers place the cost of constructing the 16 miles of line between Bessemer and Brookwood at $200,000. S. E. Jones, of this place, is interested.

OPELIKA, ALA.—The Opelika Railway, Light & Power Company has been incorporated and will build an electric road from Opelika to Auburn, a distance of ten miles. J. B. Greene, E. L. Andrews and others are the incorporators.

SAN JOSE, CAL.—The directors of the San Jose, Los Gatos & Interurban Railway Company have under consideration the proposal to establish and install a power plant in the vicinity of the present car houses. The plant will cost between $75,000 and $100,000.

VALLEJO, CAL.—The Vallejo, Benicia & Napa Valley Railroad Company has secured all the rights of way for its line from Napa to Vallejo, a distance of 16 miles. The rails have been purchased, as have also the electrical equipment, trolley poles and ties. The road is expected to be in operation about Aug. 1. The officers of the company are John Cross, president; J. W. Hartzell, second vice-president; J. E. Loomis, secretary. The main office of the company is in Los Angeles.

GREENWICH, CONN.—President Charles Singer, of the New York and Stamford Railway has inaugurated a parlor trolley service, charging double fare for seats in the parlor car and running it between Port Chester and Rye Beach.

GAINESVILLE, GA.—The Gainesville & Dahlonega Electric Railway Company, which has under way the preliminaries for the construction of an electric railway between Gainesville and Dahlonega, has organized as follows: A. J. Warner, president; W. A. Charters, vice-president; W. A. Carlisle, secretary, and J. F. Moore, of Dahlonega, treasurer.

CHICAGO, ILL.—Attorney Charles Aldrich has filed application at Washington for a writ of certoriari from the United States Supreme Court in the case attacking the validity of the Union Traction leases.

ALTON, ILL.—Representatives of J. G. White & Co., of New York, have arrived in Alton to begin preliminary work on the new interurban electric railway between Alton and St. Louis. W. T. Davis will be the superintendent of construction. Work will be commenced at once. The line will connect the Alton system with the extension of the Granite City line, which has been completed as far as Nameoki.

BELLEVILLE, ILL.—It is said that the Southern Illinois Electric Railway Company has abandoned its project for building an electric railway from Okawville through Venedy, New Memphis and Mascoutah, and thence to Belleville to connect with the East St. Louis & Suburban Railway. Donahue Brothers, of St. Louis, who had the contract for grading the line, have pulled stakes and deserted the field.

KANKAKEE, ILL.—The Kankakee Interurban Riverview Railway Company will begin within thirty days the construction of its proposed line from Kankakee to Waldron and Momence, Ill., and thence from Waldron to St. Anne. There will be 30 miles of road in all. The officers of the company are H. T. Bonfield, president and purchasing agent; J. D. Dixon, treasurer; E. W. Bonfield, secretary. The main office of the company is at Kankakee.

MARION, IND.—The Indiana Union Traction Company has acquired the Kokomo, Marion & Western Traction Company and will push the completion of the line into Marion.

CRAWFORDSVILLE, IND.—The Northwestern Traction Company is constructing a modern telephone system between this city and Lebanon, and will soon be ready for the transmission of messages by the conductors regarding the movement of trains and the other business of the company.

EVANSVILLE, IND.—The County Commissioners have granted a franchise to the Evansville & Eastern Electric Railway Company for the right of way through Knight Township. This is the proposed new line between Evansville and Rockport. The company is given the right to furnish light, heat and power in Vanderburg County.

LOUISVILLE, IND.—The Louisville & Southern Indiana Traction Company has secured possession of the Highland Electric Railway Company. The Highland Company has not been in operation for several months. It was built about fourteen years ago, and at first was a paying investment, but of late years the company lost money, and last fall the company stopped operating its cars. The purchaser will rebuild the line and make it part of its system.

EVANSVILLE, IND.—The three electric traction projects planned to run from Evansville to Rockport are pushing their respective arrangements. The survey of the Evansville & Eastern has been completed and the right of way nearly all secured. The Evansville, Booneville & Rockport has obtained a right of way and reports that the road is financed. The Evansville, Newburg & Rockport, a steam line, is to be converted into an electric road at once.

GOSHEN, IND.—Promoters of the Kalamazoo & Lake Shore Traction Company have commenced work on the line that is to connect Benton Harbor, Niles and Kalamazoo. A mortgage for $600,000 has been filed in the register of deeds office in St. Joseph by the company. The American Trust & Savings Company holds the paper and is therefore to provide the money for the construction of the road to Kalamazoo along the lake shore. Work is in progress on the line between Benton Harbor and Paw Paw Lake.

CLINTON, IA.—The Iowa & Illinois Interurban Railway Company's shops, car houses, power houses and office building will be located in this city. The company is building an interurban road between Clinton and Davenport, a distance of 42 miles. About half the grading has been completed and several miles of track have been laid.

ARKANSAS CITY, KAN.—The Kansas-Oklahoma Interurban Railway Company, which was chartered May 10, with general offices at Arkansas City, Kan., organized on May 21 as follows: W. C. Robinson, of Winfield, Kan., president; S. H. P. Northrup, of Arkansas City, Kan., vice-president and general manager; W. D. Sanders, of Arkansas City, Kan., secretary and treasurer; C. L. Brown, of Arkansas City, Kan., general attorney; T. V. Holl, of South McAlester, I. T., chief engineer.

NEW ORLEANS, LA.—A large contract has been closed by Knox, George & Co. It comprises the construction of an interurban railway line at Birmingham which will cost, when completed, about $800,000. The new road, which will be known as the Birmingham & Steel Cities Railway & Power Company, will construct 40 miles of road, which, while operated in the same general district as that covered by the older company, will open up entirely new territory. The line will run from Birmingham to such outlying cities as Ensley, Pratt City, Bessemer and surrounding towns and factory districts.

PRINCESS ANNE, MD.—The Somerset & Wicomico Power, Light & Railway Company has organized as follows: Fillmore Lankford, of Princess Anne, president; Lloyd Riggin, of Crisfield, secretary, and S. Frank Dashiell, of Dames Quarter, treasurer. A committee has been appointed to select a route between Salisbury and Crisfield.

GRAND RAPIDS, MICH.—The contract for building the Grand Rapids & Ionia Electric Railway has been let to the Farnham Construction Company, of Chicago, work to commence before July 1 and to be completed not later than March 1, 1905. The power house will be located at Saranac, from which place construction will be pushed in both directions.

MINNEAPOLIS, MINN.—The Pioneer Electric Railway Company, of Minneapolis, has been incorporated with a capital stock of $100,000, to construct an electric railway from White Rock to Minneapolis and St. Paul. The incorporators are P. W. McAllester, Herman F. Johnson, Fremont D. Woodbury and B. F. Cooper, of Minneapolis, and Anton W. Holmes, of St. Paul.

KANSAS CITY, MO.—A sub-station is being built by the Metropolitan Street Railway Company at Twelfth Street and Cleveland Avenue. It will supply several of the East Side car lines with power. When this work is completed the Blue River power plant will be overhauled and improved.

ST. LOUIS, MO.—The United States Railways Company's electric rolling stock in St. Louis County has been assessed at $40,000; 2.43 miles of double track on public highways at $12,000 a mile; 6.54 miles of single track on public streets at $6000 a mile; 14.33 miles of double and 3.88 miles of single track private right of way at $12,000 and $6000 a mile, respectively. St. Louis and Suburban, 11.766 miles of single track at $6000 a mile, and improvements, $58,000. St. Louis and Kirkwood, 12.477 miles at $8000 a mile, and improvements, $37,150. St. Louis and Meramec River Railway Company 13,422 miles at $12,000 a mile, and improvements, $33,000. Brentwood, Clayton and St. Louis, 12.489 miles at $10,000 a mile, rolling stock, $12,000. St. Louis, St. Charles and Western, 15.567 miles of single track at $6000 a mile.

OMAHA, NEB.—The Omaha, Lincoln & Beatrice Railway, which plans to build an electric railway to connect Omaha, Lincoln and Beatrice, has filed with the Secretary of State articles increasing its capital stock from $200,000 to $2,250,000. Henry Robinson, of Akron, Ohio, is president. Contracts for equipment, it is stated, have been closed.

NEW YORK, N. Y.—The board of estimate and apportionment has voted unanimously in favor of accepting the report made by Comptroller Grout giving the New York, Westchester & Boston Railway Company the right of an entrance over the streets of the city, and compensation to be paid for the same.

NIAGARA FALLS, N. Y.—The Thorold & Lake Erie Railway Company has a bill before the Canadian Parliament to permit it to construct an electric railway from Thorold to Welland and thence to Port Colborne and Buffalo; also a line to Brantford. The idea is to operate the electric railway so that passengers passing through the Welland Canal on any of the Wolvin Company's boats, may make a side trip to the falls by electric railway and meet the boat farther down the canal. The bill is meeting with a great deal of encouragement.

CLEVELAND, OHIO.—A franchise has been granted by the City Council to a proposed street railway company, which is to charge a 3-cent fare. It is the first franchise of its kind in the city. Mayor Johnson is said to be interested in the new line, which, according to the conditions of grant, must be in operation by April 1, 1905.

BAKER CITY, ORE.—Of the proposed issue of $5,000,000 bonds of the Baker City & Oregon Wonder Electric Railway and Improvement Company, $500,000 was recently negotiated by Major Bonta, the promoter, the bonds having been taken by the North American Trust Company of New York. The railway company plans the construction of a system which will extend from this city throughout the southern portion of the state and finally connect with a transcontinental system in Nevada or California. The first line to be built will be to Prairie City, a distance of eight miles, and it is estimated that in this undertaking $750,000 will be expended on construction work and equipment. This does not include the power plants which are planned by the company, although not for the immediate future. Branch lines will be run from the main line to numerous small towns in Southern Oregon.

GREENVILLE, PA.—The Greenville Street Railway Company has been incorporated. William C. Wibert and Samuel G. Bailey, of Pittsburg, are interested.

CONNELLSVILLE, PA.—It is reported that the Pittsburg, McKeesport & Connellsville Street Railway has decided to build a line from Leckrone to Masontown.

JOHNSTOWN, PA.—A charter has been issued at Harrisburg for the Pennsylvania Street Railway Company to build an electric railway from Spangler to Moss Creek, a distance of three miles. The company has a capital of $18,000. F. Marstaller is president. The Pennsylvania Coal Company is understood to be interested in the project.

LANCASTER, PA.—The stockholders of the Lancaster & Mount Joy and Lancaster & Rohrerstown electric railways have decided to merge the two companies into one under the name of the Lancaster, Rohrerstown & Mount Joy Railway Company. The officers elected are Charles B. Keller, president; John S. Graybill, Jr., secretary and treasurer.

DANVILLE, PA.—The Danville & Bloomsburg Electric Railway Company has commenced the construction of its proposed road to extend from Danville to Bloomsburg, a distance of 10 miles. As soon as the bridge over the Susquehanna River is rebuilt the line will extend to South Danville and thence to Snydertown, where it will connect with the proposed Shamokin & Sunbury line.

CLEARFIELD, PA.—An ordinance has been introduced in the Town Councils of Clearfield and Curwensville, granting a franchise to the new Clearfield & Curwensville Street Railway Company. The proposed line will be 12 miles in length. The officers are E. A. Irvin, of Curwensville, president; W. H. Denlinger, R. D. Swope, C. E. Patton, A. W. Lee, F. G. Harris, W. I. Betts, E. W. Hess, F. G. Betts and T. L. Snyder, directors.

CHAMBERSBURG, PA.—The engineering corps of the proposed Catoctin & Myersville Electric Railroad has completed the survey to Pen Mar, where connection is made with the Chambersburg, Gettysburg & Waynesboro Electric Railway. The line as surveyed for the Catoctin & Myersville road runs from the Frederick-Middletown line at Myersville to Pen Mar station, on the Western Maryland Railroad, a distance of 22 miles. The corporation of the new road has elected the following officers: J. H. Maugans, president; A. L. Hauver, vice-president; H. H. Warrenfeltz, secretary; Charles U. Grossnickle, treasurer.

NASHVILLE, TENN.—A meeting of the promoters of the Nashville & Columbia and the Nashville & Gallatin interurban lines was held a few days ago, at which officers and directors were selected. The capital stock of the former road was increased from $50,000 to $2,000,000, and of the latter from $50,000 to $2,000,000. The following officers were elected; Nashville & Columbia, H. M. Gross, of Pittsburg, president; Thos. E. Perry, Jr., of Pittsburg, vice-president Nashville & Gallatin, H. M. Gross, of Pittsburg, president; Thos. E. Perry, Jr., of Pittsburg, vice-president; J. H. Connor, general manager. John H. Connor has accepted the contract for building the road from Nashville to Franklin, and the building of the power house at this point and two substations along the way.

DALLAS, TEX.—A movement is on foot to build an interurban electric railway from this city to Grand Saline, Tex., a distance of about 65 miles. A number of Dallas capitalists are interested in the project.

HOUSTON, TEX.—The charter of the Houston-Galveston Interurban Railway Company has been filed. The company is formed for the purpose of building an electric railway between Houston and Galveston, a distance of 51 miles. It has a capital stock of $250,000. The directors are James R. Patton, of Kansas City; Charles D. Graham, of Fairview, Kan.; T. W. Allen, of Greenup, Ill.; Walter Gresham, of Galveston; O. M. Whitcomb, of Webster, Tex.; W. E. Scott, W. B. Slosson, N. C. Abbott and J. Edgar Lafferty, all of Houston. The principal office is in Houston.

NORFOLK, VA.—Stockholders of the Chesapeake Transit Company have authorized an increase of capital stock from $1,000,000 to $1,500,000. This money will be used in carrying out improvements.

RICHMOND, VA.—The Citizens Rapid Transit Company has completed all details for building a new trolley line in Richmond from Brook Avenue to Fulton and the contracts have been let for the material and work. The new road complete will represent an outlay, it is said, of over $500,000. The new company has been quietly organized by Richmond and Northern capitalists, and is most substantially backed.

ST. ALBANS, VT.—At the annual meeting of the stockholders of the Mount Mansfield Electric Railway Company, the following officers were elected: A. H. Soden, president; C. D. Pike, vice-president; L. C. Moody, of Waterbury, secretary; W. B. McCutcheon, treasurer; F. L. Shepard, general manager.

PARKERSBURG, W. VA.—The Parkersburg, Marietta & Interurban Railway Company is extending its present power station at Parkersburg, W. Va., and installing Westinghouse-Parsons steam turbines. A 400-kw unit will be installed for the present which will operate on 150 lbs. steam and 28 inch vacuum. Steam will be furnished by water tube boilers without superheater. The generator will furnish 2-phase, 60-cycle current at 2200 volts to a single-phase distribution system supplying current for local lighting. The turbine unit will operate in parallel with the present equipment of the plant, which consists of Westinghouse compound engine generating outfits of the belted type.

New Industrial Companies.

THE GEMMILL TELEPHONE COMPANY has been formed at Barberton, Ohio, and will commence the erection of a factory building to manufacture telephones.

THE CENTRAL CALIFORNIA ELECTRIC COMPANY has been incorporated at Tuolumne with a capital stock of $500,000, and the incorporators are J. L. Gibbs, G. G. Grant and J. E. Conde.

THE TRITT ELECTRICAL MANUFACTURING COMPANY, of South Bend, Ind., has filed articles of incorporation with the Secretary of State. The capital stock is $15,000. The directors are B. S. Tritt, A. H. Calvert and C. H. Kreighbaum.

THE ELECTRICAL & CHEMICAL GAS COMPANY, of Harrison, N. J., has been incorporated with a capital stock of $50,000. The incorporators are John A. Yunck, Harry H. Yunck, Millard F. Wellford, Edward G. Nessley and Joseph R. Welfong.

THE IMPERIAL CONSTRUCTION COMPANY, of Charleston, W. Va., has been incorporated to build and operate telephone, telegraph and electric light plants. The capital stock is $50,000, and the incorporators are Homer P. Dixon, E. P. Lowler, James E. Furguson, Harlan W. Gillis, all of Charleston.

Obituary.

JAMES A. MYERS.

MR. JAMES A. MYERS, president and treasurer of the Robbins & Myers Company, of Springfield, Ohio, died at his home in that city on May 27. He had returned on April 22 from an extended business trip and seemed at that time in the best of health. He became ill on May 7, however, and soon developed symptoms of typhoid fever which terminated fatally as noted. Mr. Myers was born at Jamestown, Ohio, in 1851, and was educated at Bowersville Academy. He went to Springfield in 1876 and engaged in business. In 1878 he became interested with Mr. Robbins in the iron foundry business, in 1889 forming the present Robbins & Myers Co., and becoming its president on the retirement of Mr. Robbins in 1900, an office he occupied at the time of his death. Mr. Myers became actively interested in electrical affairs in 1896, about which time his company entered the electrical manufacturing field. From this time his acquaintance among members of the electrical fraternity increased rapidly, until at the time of his death he numbered among them many friends in all sections of the country. Mr. Myers was quite successful in affairs and to his energetic and careful management the prominent position of his company is largely due. He leaves a wife and two sons.

Educational.

LECTURE ON MACHINE SHOPS.—An interesting and instructive lecture was delivered on "The Modern Machine Shop," before a large and representative audience at the Carnegie Music Hall, Pittsburg, Pa., Monday evening, May 16th, by Mr. Charles Day, of the firm of Dodge & Day, Philadelphia, Pa., under the auspices of the Carnegie Technical Schools, not the least interesting part of which was that dealing with the early history of the machine shop. The work done by such pioneers as Watt, Maudslay, Nesmyth and Whitworth was briefly reviewed and some of the original machines designed by them illustrated. The evolution up to the present day was traced through its various stages and graphically illustrated by lantern slides. Mr. Day was introduced by Mr. Frank H. Taylor, vice-president of the Westinghouse Electric & Manufacturing Company.

Legal.

SELF-RESTORING SWITCHBOARD DROPS.—In a communication received from Mr. James A. Keelyn, attention is called to the recent decision of the United States Circuit Court of Appeals in sustaining the patents of the Western Telephone Manufacturing Company covering self-restoring switchboard drops; the effect of which decision, it is stated, is being minimized by some patent attorneys, patent experts and manufacturers of self-restoring drop switchboards. The communication states that these patent attorneys, experts and manufacturers previously claimed that the patent would not win and that their present action is to further mislead the public.

Personal.

MR. C. O. MAILLOUX, consulting engineer, Bishop Building, William Street, New York, is on a trip to Europe. He is expected to return in about a month.

MR. GEORGE WOOD BACON, of Ford, Bacon & Davis, consulting engineers, was married June 1 to Miss Caroline Tilden Mitchell at St. Cloud, Minn., the residence of the bride.

PROF. GEO. D. SHEPARDSON is represented in the current issue of the *Year Book* of the Society of Engineers, University of Minnesota, by a paper entitled "The Electrostatic Capacity of Wires."

MR. RALPH BEACH, well known in the General Electric Company, has returned to New York from a trip to Mexico, where he is very largely interested in the Tula Iron Works, whose equipment is being modernized on American lines.

MR. GORDON M. ARNOLD, brother of Mr. B. J. Arnold, president of the American Institute of Electrical Engineers, has received an appointment to West Point and successfully passed the physical and mental examinations for admission.

MESSRS. LINCH & SPROEHNLE, Pennsylvania Building, Philadelphia, have been retained as consulting and contracting engineers for the new electric railway to be constructed between Palmyra, Valley Glen and Grantville, Pa. Work will be commenced at once.

DR. LEE DE FOREST, of wireless telegraph fame, whose system is now being used so successfully by the *London Times* and *New York Times* off Port Arthur, is the subject of an appreciative sketch in the London *Daily Mail* of recent date, his portrait and apparatus being shown.

MR. F. S. PEARSON, vice-president and consulting engineer of the Mexican Light & Power Company, the Canadian syndicate which is building the huge Necaxa, Mexico City, El Oro power transmission system, is back in New York from a trip to the Southern Republic, to inspect the progress made on the work.

NOYES BROTHERS, of Perth, Australia, have been appointed engineers to the Freemantle and East Freemantle Municipal Councils to design and construct a complete system of municipal electric tramways and lighting. The estimated cost of these works is $420,000, and the system is to be ready for operation in about eighteen months.

MR. A. E. MITCHELL, formerly associated with high tension work in Denver, Col., has been appointed superintendent of motive power of the Lehigh Valley Railroad Company with headquarters at Bethlehem, Pa. He has charge of the entire specifications for the equipment of new shops at Sayre, Pa., which call for a large quantity of electrical equipment.

MR. SALVADOR UGARTE, of the Mexican electrical engineering and contracting firm of Ugarte & Garcia, of Guadalajara, State of Jalisco, which has contracts in hand for the construction and equipment of electric plants in the western part of the Southern Republic entailing an expenditure of fully $500,000 for machinery, sailed this week for Europe, but expects to be back in about three weeks, when he proposes to close contracts here for the equipment.

MR. EDWARD B. ELLICOTT, city electrician of Chicago, who has acted as constructing, electrical and mechanical engineer at the Louisiana Purchase Exposition since last December, has returned to Chicago, having practically completed his work at the Exposition, where he made a record in installing an immense amount of electrical apparatus in a very short time. The Exposition Company's electrical service construction has been well in advance of the other work.

MR. L. E. BENNETT has been appointed superintendent of construction on the extensive harbor improvements at Iloilo and Cebu, Philippine Islands, the contracts for which were recently awarded by the Government to J. G. White & Company. Mr. Bennett some time acted for the Siamese Government on the construction of the electric lighting system in Bangkok, the capital city of Siam. He also installed Yankee lighting equipment in the King's palace. He left the Government engineering bureau in Manila in order to take up his new position.

MR. MASON D. PRATT has opened an office at 18 North Third Street, Harrisburg, Pa., to do a general engineering business, including surveys, plans, etc., and construction for electric railways, power plants, etc. Mr. Pratt is a graduate of Lehigh University, and was with the Phœnix Bridge and Johnson companies. For some 13 years he was with the Pennsylvania Steel Company as street railway engineer, etc., and was in charge of the construction of a power plant for them of 1000-hp, electric sub-stations, etc.

MR. E. N. FOBES, of the Fobes Supply Company, Seattle, Wash., will be in New York next week for the purpose of placing orders for shipment July 1, 1904, March 1, 1905, for 100,000 incandescent lamps, 7000 iron-box bells, 27,000 Edison key sockets, 10,000 dry batteries, 10,000 insulator joints, 50,000 enclosed arc lamp carbons, a substantial lot of flexible and iron armored conduits and a general line of electrical supplies. While in New York he will make his headquarters in the offices at 136 Liberty Street of Mr. T. D. Watson, local representative of the Trumbull Electric Company.

MR. RUDOLPH MIEHLING, formerly New York manager of the Walker Electric Company, has connected himself with the Frank Adam Electric Company, of St. Louis, as sales manager.

MR. J. H. HALLBERG has opened offices at 45 Broadway, New York City, as a consulting electrical engineer and lighting expert. The telephone call is 4578 Broad. Mr. Hallberg has done a large amount of excellent work in late years in the lighting field.

MR. ARTHUR WARREN has an able and very interesting article in the June *American Review of Reviews* on "The Turbine: A New Era in Steam." It is written with his wonted literary skill and is well illustrated. The subject is summed up and discussed in a way that makes it thoroughly intelligible to the general public.

PROF. E. F. NICHOLS.—Professor Ernest Fox Nichols, of Columbia University, has received the Rumford gold and silver medal for marked scientific research. The honor was awarded Professor Nichols not only by the American Academy of Arts and Sciences, but also by the British Society, thus making the distinction a double one. Professor Nichols's research was directed along the lines of radiation, especially in the field of the pressure due to radiation, the heat of the stars and the infra-red spectrum. The medal will be struck off this summer, and will be presented to Professor Nichols at a special meeting of the American Academy of Arts and Sciences.

MR. MAX LOEWENTHAL, secretary and electrical engineer of the Prometheus Electric Company, has returned east from a four-months' trip in the interests of this company, having during that time visited almost every large city in the United States as far west as Denver, Col., establishing agencies for the sale of Prometheus electric heating and cooking apparatus. In the opinion of Mr. Lowenthal, after having thoroughly canvassed the situation, the immediate prospects of the electric heating business are very encouraging. In addition to an active business trip, Mr. Loewenthal enjoyed an excursion through the mining camps of Colorado and a trip to the St. Louis Exposition.

MR. PAUL M. MOWREY, who for the last three years has been connected with the Merchants' Trust Company as adviser on industrial investments, has assumed the office of vice-president of the Engineering Company of America, 74 Broadway. He has been prominently identified with the engineering and contracting business since 1888, when he became connected with the Edison Illuminating Company. Among his numerous successful enterprises was the purchase and consolidation of the street railway and power companies of Richmond, Va., which were later turned over to Mr. Frank Jay Gould.

MR. C. C. TYLER has resigned his position as superintendent of the works of the Westinghouse Electric and Manufacturing Company, at East Pittsburg, Pa., and has been appointed general superintendent of all the works of the Allis-Chalmers-Bullock interests in the United States. Mr. Tyler, who will enter upon his new duties on June 15, will make his headquarters at Milwaukee. His record in the practical management of great machine-shops is well known. Before Mr. Tyler went to Pennsylvania he made an excellent reputation, and at Pittsburg, where he has been for half dozen years, he enhanced this by the results he achieved in his work there. In the equipment of manufactories, in the design and construction of machine tools, in the handling of machinery and material in processes of manufacture, and in fact in all that pertains to the economy of machine-shop administration, Mr. Tyler is recognized as an expert who has no superior in this country. In entering upon his new field of duty, he is sure to carry with him the congratulations of the engineering profession. His appointment is another evidence of the care and strength by which the Allis-Chalmers Company organization (which, it will be remembered, now also controls the Bullock Electric Manufacturing Company) is being wrought together.

PROFESSOR A. MARSTON, who has been in charge of the civil engineering department for the last twelve years, was recently elected Dean of the Engineering Division at the Iowa State College. Professor G. W. Bissell has charge of the Department of Mechanical Engineering, Professor L. B. Spinney of the Electrical Engineering, and Professor S. W. Bayer of the Mining Engineering. The idea is to unify the work of the departments. During the last few years they have been experiencing a remarkable growth and the enrollment the present year is six hundred and seventy (670) students. This is an increase of about five hundred per cent. in seven years, and, taken in connection with the completion and occupation of the new $220,000 Engineering Hall, has brought the Division of Engineering to such a point that it seemed wise to have a more centralized organization. The engineering departments secured from the legislature a small appropriation for the establishment of an engineering experiment station to conduct experimental researches and publish bulletins helpful to the industrial interests of the State. The college also secured an appropriation of $7000 for good roads' experimentation and a law was passed by the legislature making the college a state highway commission. This work also will fall largely to the Division of Engineering, although the Agricultural Division will work in co-operation. It is the intention, among other things, to establish a summer good roads school for the benefit of road officials of the State. Professor Marston is a graduate of Cornell University, class '89.

DR. F. W. ATKINSON, the new head of the Brooklyn, N. Y., Polytechnic Institute, is a man of fine and engaging personality and already well known as an instructor. He was born on May 23, 1865, at Reading, a suburb of Boston. He graduated from the Reading High School and for four years from 1882 studied at the State Normal School, Bridgewater, Mass. Upon graduation from that institution he became principal of the Upton, Mass., High School, in which position he remained a year. Further studies were pursued at Harvard during the next three years, and in 1890 he received the degree of A. B. The following year he was in charge of the Westfield, Mass., High School. Then he went abroad to get advantage of foreign teaching, methods and experience. He studied at the Universities of Berlin, Halle and Leipsic for two years, taking the degree of Ph. D. at Leipsic. The next year he studied at Jena University and at the Sorbonne, Paris. During this stay in Europe Dr. Atkinson visited schools of all sorts in Germany, Austria and France. In 1894 he became principal of the Springfield, Mass., High School, holding the position until May, 1900. In that month, on the recommendation of President Eliot, the Hon. W. T. Harris and the Hon. C. D. Wright, he was appointed by the U. S. Philippine Commission as General Superintendent of Public Instruction in the Philippine Islands. It was wh[illegible] that Dr. Atkinson came most prominently before the public. His service there was purely pioneer and constructive, and the educational policy adopted by the United States in the archipelago was almost entirely his in both conception and execution. In June of last year, on his return from the islands, Dr. Atkinson was immediately appointed Superintendent of Schools at Newton, Mass., which position he now holds.

Trade Notes.

THE C. J. TOERRING COMPANY has removed its offices and factory to 2318 Noble Street, Philadelphia.

THE MORRIS ELECTRIC COMPANY, of Wilmington, Del., is issuing a catalogue which runs for one year from April to March. The 1904 production contains a pretty figure, and a simple announcement of fibre specialties and fibre wiring cleats.

SMITH ELECTRIC STORAGE BATTERY.—The Smith Storage Battery Company, Binghamton, N. Y., in a circular, illustrates and describes the Smith storage battery. Several large installations of the battery, which is of the superposed tray type, are illustrated.

TELEPHONE PAY STATIONS.—With the title "A Bargain in Pay Stations," the Kellogg Switchboard & Supply Company, Chicago, is sending out an announcement of reduced prices for pay stations in order to close out the stock in hand, the manufacture of this class of apparatus having been discontinued.

THE CANADIAN WESTINGHOUSE COMPANY has issued a tasteful circular in English and French editions as to the large works it is putting up at Hamilton, Ont., to build all kinds of Westinghouse apparatus, employing, however, only Canadian labor and material. Over a thousand men will be employed.

THE RITTENHOUSE-MILLER COMPANY has removed its factory from Philadelphia to Trenton, N. J., thus increasing its facilities for the manufacture of Eureka flexible conduit, the steadily increasing demand for Eureka conduit having necessitated this change. The address of the company will henceforth be Trenton, N. J.

ELECTRIC STORAGE BATTERY LOCOMOTIVES.—The C. W. Hunt Company is sending to its friends and patrons a neatly printed invitation to make a visit when at St. Louis to its exhibit of electric storage battery locomotive and cars running on narrow gauge "Industrial" tracks with curves and switches of 12 feet radius.

MACHINERY HALL, unlike the other buildings at the St. Louis World's Fair, is not closed in the evening. It is open until 11 p. m., and visitors in the evening find at work there, among other objects of interest, the big 5000-hp Allis-Chalmers-Bullock engine and generator producing the electric current to keep aglow the 120,000 or more decorative lights which glitter all over the buildings and grounds.

THE DIALECTRIC MFG. COMPANY, of St. Louis, has issued a four-page folder on its W. D. paint, which it says is proof against rust, dampness and electrolytic action. This is a quick-drying black paint affording a permanent insulation protection to wood or metal. Another pamphlet which it has issued speaks of "dielac" which is sticking varnish; "dilectrol," which is for copper coils, and dielectric varnish, which is a baking varnish.

THE WILLIAM B. POLLOCK COMPANY, Youngstown, Ohio, builders of all kinds of steel plate construction, has installed a modern hydraulic flanging plant of the largest size built. This additional equipment enables the company to bend and form the heaviest sections of structural material as well as flange and bend plates up to 2½ inches thick. With this latest acquisition, the William B. Pollock Company's plant is all the more equipped for the erection of heavy steel plate construction for all purposes.

VOUGHT-BERGER FIRE.—On Saturday night, June 4, the factory of the Vought-Berger Company, La Crosse, Wis., was practically destroyed by fire. The fire was first discovered in the assembly rooms on the second floor of the main factory building and ruined a large portion of the work in progress in the telephone and switchboard departments. Fortunately, however, the machine shops, wood-working plant and the plating and the buffing departments were uninjured. All the buildings remained intact and the machinery, tools, dies and jigs and also raw materials and reserve stock were in no way damaged. The loss is placed in the neighborhood of $7000 or $8000. The company was, fortunately, on the verge of making many improvements and enlargements to handle the unprecedented amount of new business, and these plans will be carried out at once. The company states that the delay in shipments will be not more than a week, and that absolutely no damaged material will be delivered to any of its customers.

DRY BATTERY FANS.—Electric fans have ceased to be a luxury and have become a necessity, but every house is not provided with electric current with which to run a fan. This deficiency has been met by the Jones Fan & Motor Company, 62 Vesey Street, New York, in its dry battery fan outfits. The battery and fan are made for each other, so that the best results are obtained from each. The "dry" feature of the battery commends the use of the outfit in the home, as there is no danger from spilling of chemicals, etc. The company guarantees a power-life of the battery of 250 hours with ordinary use of the fan. The battery box contains 20 cells of dry battery, and the fan, being especially designed for this combination, gives a powerful breeze. All those desiring to enjoy the comforts of a cooling breeze, but who have no electric power available to operate a fan, would do well to investigate the merits of this outfit.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED MAY 31, 1904.

[Conducted by Rosenbaum & Stockbridge, Patent Attys., 140 Nassau St., N. Y.]

761,066. LIGHT ACCUMULATOR FOR CONTINUOUS AND ALTERNATING ELECTRIC CURRENTS, August Engelsmann, Stuttgart, Germany. App. filed Aug. 1, 1902. Details of an apparatus for focusing the light of an electric lamp upon a parabolic mirror.

761,090. HIGH TENSION ELECTRIC CONDENSER; Ignacy Moscicki, Fribourg, Switzerland. App. filed Feb. 17, 1904. The improvement consists in the parts of the dielectric which support the edges of the coatings being considerably thicker than the remaining parts covered by the coatings.

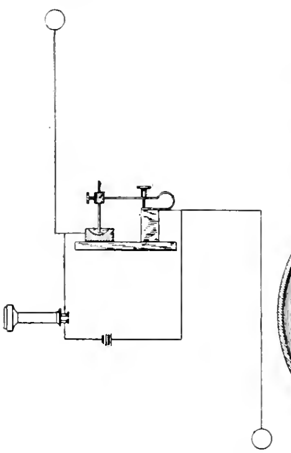
761,094. FUSE; Wm. McElroy, Brooklyn, N. Y. App. filed April 2, 1900. Means controlled by the opening of a main switch for automatically introducing one of the cut-outs into the circuit when a preceding cut-out has operated to break the circuit.

761,102. INSULATOR; Leonard M. Randolph, Newark, N. J. App. filed March 12, 1903. A base and a cap forming between them a channel for the cable and having projections in the line of the channel around which clamps are placed to hold the parts of the insulator together.

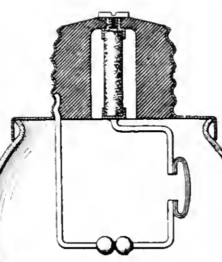
761,111. PRODUCTION OF TUBES FROM REFRACTORY MATERIAL; Elihu Thomson, Swampscott, Mass. App. filed Aug. 28, 1902. A pair of electrodes are surrounded by the refractory material in a divided state and by drawing a gradually lengthening arc the material is fused and forms a tube.

761,117. ELECTRICAL REGULATING MECHANISM; Allyn B. Walton, Lorain, Ohio. App. filed June 25, 1902. The mechanism embodies an electromagnet having two sets of poles forming two magnetic fields, one of such fields being of greater impedance than the other, in connection with a movable coil in series with the magnet coil.

761,133. ELECTRIC SWITCH; Henry P. Ball, New York, N. Y. App. filed Sept. 30, 1902. Relates to the mounting of the oil tank at the back of the switchboard and the construction of the operating mechanism connected therewith.



761,450.—System of Telegraphy.



761,380.—Electric Arc Lighting.

761,134. AUTOMATIC SHORT CIRCUIT ALARM FOR ELECTRICAL GAS LIGHTING OR OTHER SYSTEMS; Ferdinand M. Barrell, Brooklyn, N. Y. App. filed June 15, 1903. Details.

761,150. TELEPHONE ATTACHMENT; George A. Cowgill, Euphemia, Ohio. App. filed July 16, 1903. (See page 1125.)

761,182. ELECTRIC ARC LAMP; Joseph A. Rignon, Berlin, Germany. App. filed Aug. 21, 1902. Details.

761,198. HEAT ACTUATED ALARM SYSTEM; Charles E. Buell, Camden, N. J. App. filed May 28, 1903. Details.

761,199. APPARATUS FOR PRODUCING AN ALTERNATING MAGNETIC FIELD FOR THERAPEUTIC PURPOSES; Ernst Buhtz, Berlin, Germany. App. filed Jan. 30, 1904. Two or more magnets arranged about a common shaft, the lines of force passing between their poles producing on rotation of the apparatus a vortex of lines of force which is said to improve the therapeutic properties of the magnetic field.

761,204. METHOD OF MAKING ELECTRICAL HEATING APPARATUS; Charles E. Carpenter, New York, N. Y. App. filed Nov. 20, 1902. The insulating material while in a molten state is compressed between two metal plates, the heating conductor being at the same time embedded in the material.

761,205. ELECTRICAL HEATING APPARATUS; Charles E. Carpenter, New York, N. Y. App. filed Jan. 27, 1904. The apparatus patent conforming to the method described in the preceding patent.

761,208. RAILWAY SIGNAL; John P. Coleman, Edgewood, Pa. App. filed Sept. 4, 1903. The signal is operated pneumatically from a distance by electro-magnetic apparatus.

761,230. WEATHERPROOF POLE SWITCH; Chester H. Jackson, Portland, Me. App. filed May 29, 1903. Details.

761,250. ELECTRIC HEATER; Edwin F. Porter, Boston, Mass. App. filed Oct. 17, 1898. A heating conductor is wrapped around the blades of an electric fan.

761,256. WIRELESS TELEGRAPHY, Charles K. Salisbury, Lincoln Township, Blackhawk County, Ia. App. filed Oct. 30, 1902. Means for sending two or more messages simultaneously to an equal number of stations and means for utilizing relays for sending messages to stations outside of the electrical influence of the transmitting station.

761,258. WAVE RECEIVER; Richard W. Shoemaker and Lawsen H. Giddings, Pasadena, Cal. App. filed May 2, 1902. The receiver is susceptible to the electrical waves continuously, the susceptibility not being destroyed after each wave is received; the receiver consists of a conducting medium comprising particles of conducting material mixed with particles of non-conducting material.

761,267. MAGNETO; Walter F. Taylor, Brookline, Mass. App. filed Feb. 19, 1904. A polished finishing plate is placed over a coating of protecting material applied to the outer surface of the magnet.

761,280. POTENTIAL INDICATOR FOR HIGH VOLTAGE CIRCUITS; Jonathan E. Woodbridge, Albany, N. Y. App. filed Oct. 30, 1902. By inserting condensers in the leads between the main lines and the instruments, it is rendered safe to operatives to mount the instruments upon the switchboards.

761,284. REDUCTION OF NITRO COMPOUNDS; Max Buchner, Mannheim, Germany. App. filed Dec. 13, 1902. (See page 1125.)

761,308. TROLLEY WHEEL GUARD; Curtis W. Leslie, Pittsburg, Pa. App. filed Nov. 5, 1903. Details.

761,310. PREPARATION OF AZO DYES; Walther Loeb, Bonn, Germany. App. filed March 16, 1903. (See page 1125.)

761,345. STORAGE BATTERY; Theodore A. Willard, Cleveland, Ohio. App. filed Sept. 11, 1903. (See page 1125.)

761,360. ELECTROPNEUMATIC BRAKE; John W. Cloud, London, Eng. App. filed Sept. 30, 1901. An ordinary automatic air brake system with means whereby it can be actuated when necessary by electrically controlled valves.

761,372. PORTABLE ELECTRIC GAS LIGHTER; Edwin R. Gill, New York, N. Y. App. filed Jan. 4, 1902. Details.

761,379. ELECTRIC ARC LAMP; John A. Heany, York, Pa. App. filed Dec. 4, 1903. An arc lamp operating on the principle of the Nernst lamp, the electrodes being non-conducting when cold and an initial current serving to heat them up and at the same time separate them to strike the arc.

761,380. ELECTRIC ARC LIGHTING; John A. Heany, York, Pa. App. filed Feb. 4, 1904. The method corresponding to the previous patent.

761,417. SAFETY APPARATUS FOR USE ON RAILWAY CARS; Sidney H. Short, London, England. App. filed Feb. 11, 1902. In case the insulation of the trolley pole and base breaks down, an alarm is automatically sounded so that passengers on the roof of the car may be removed before any one comes in contact with the trolley pole.

761,432. COLLECTOR FOR THIRD RAIL SYSTEMS; Aldred K. Warren, New York, N. Y. App. filed Feb. 25, 1903. The shoe being at the end of a pivoted arm, is electrically connected with the car circuit by a flexible conductor wound around the axis of the arm.

761,450. SYSTEM OF TELEGRAPHY; John L. Creveling, New York, N. Y. App. filed April 11, 1903. The receiving device is a conducting bath, which is normally of high resistance, but which by electrolysis becomes of lower resistance on the passage of the received wave, and thus affects the local circuit, including the receiving device.

761,454. MANUAL AND AUTOMATIC CIRCUIT CONTROLLER; Wm. L. Denio, Rochester, N. Y. App. filed Jan. 20, 1904. Details.

761,459. SYSTEM FOR OPERATION OF MAGNETIC CLUTCHES; Arthur C. Eastwood, Cleveland, Ohio. App. filed Jan. 14, 1904. Means whereby the clutch magnets are strongest at the time of completing the circuit through them and while the load is being accelerated, the current being afterwards economized and preventing over-heating of the clutch.

761,466. ELECTRIC CUT OUT; Philip H. Fielding, New York, N. Y. App. filed Oct. 10, 1903. A double-pole cut-out in which the switch members are located in deep grooves or cavities in the face of an insulating block, the circuit closing member itself being an inclosed fuse of ordinary type which is readily removed when destroyed and substituted by another.

761,490. SAFETY DEVICE FOR ELECTRIC INTERLOCKING OR BLOCK SIGNALING APPARATUS; Frederick T. Hollins, Leytonstone, Eng. App. filed Feb. 18, 1901. A current-arrester is placed upon the circuits to prevent stray high-tension currents from getting on to the signal circuits.

761,526. INSULATED RAIL JOINT; James C. Mock, Detroit, Mich. App. filed Oct. 26, 1903. A heavy section of rail is fixed to the side of a main rail so that its upper surface will be flush therewith and afford a contact surface for the car wheel for signaling purposes.

761,533. SPRING CLIP; John S. McKee, Pittsburg, Pa. App. filed Oct. 17, 1903. In a switch where two blades connect with the clips at each pole, the intermediate clips are made shorter than the other clips to prevent an arc from forming and melting the inner surfaces of the blades, producing thereon a blister which would prevent the blade from entering the clip.

761,536. AUTOMATIC CAR SWITCH; Morris Nuss, Philadelphia, Pa. App. filed Sept. 25, 1903. Details.

761,549. ELECTRIC RAILWAY CROSSING; Abraham A. Shobe and William Embley, Jerseyville, Ill. App. filed Sept. 26, 1903. A cast box containing insulating material in which the crossing conductors are embedded and from which the latter project to engage with the conductors approaching the crossing.

761,553. THIRD RAIL SUPPORT; Louis Steinberger, New York, N. Y. App. filed Dec. 7, 1903. The insulator upon which the third rail rests contains a conical cavity into which a supporting pin projects, affording certain lateral free movement of the insulator on its support.

761,563. SWITCH FOR ELECTRIC LAMPS; Charles Wager, New York, N. Y. App. filed Aug. 22, 1903. Details.

761,565. TROLLEY MECHANISM; John H. Walker, Lexington, Ky. App. filed July 29, 1903. Details of construction whereby a flexible conductor is connected between the trolley base and pole.

761,566. TROLLEY; John H. Walker, Lexington, Ky. App. filed July 29, 1903. Details.

761,567. TROLLEY; John H. Walker, Lexington, Ky. App. filed Dec. 24, 1903. In addition to the wheel a sliding shoe is provided and mounted to the rear of the wheel in a pivoted yoke.

761,572. ELECTRIC FIRE AND BURGLAR ALARM; Wm. C. Barger, Mammoth, W. Va. App. filed March 31, 1904. Details.

761,574. TROLLEY PROTECTOR; John H. Best, Jr., Sandusky, Ohio. App. filed Jan. 8, 1904. Details.

761,611. TROLLEY POLE; Charles F. Ritchel, Bridgeport, Conn. App. filed Sept. 17, 1903. The wheel is mounted in an extension to the pole which is connected therewith by a vertical axis permitting lateral play of the wheel with respect to the pole.

761,616. SELECTIVE PARTY-LINE TELEPHONE SYSTEM; Albert J. Springborn, Cleveland, Ohio. App. filed June 27, 1902. (See page 1125.)

761,636. AUXILIARY FIRE ALARM SYSTEM; Wm. L. Denio, Rochester, N. Y. App. filed Jan. 20, 1904. Details.

CONTENTS.

Electrified Passenger Traffic.

The effect of electricity upon the development of street railway traffic has often been referred to, but is again emphasized in the figures brought out by the 1904 edition of "American Street Railway Investments," which is reviewed in our columns this week. This excellent compendium gives among other things a summary of the earnings of 310 street railway companies in the United States; and very interesting data are included. The number of those reporting receipts of over $1,000,000 annually has increased from 38 to 42, and all of these companies show an increase in gross receipts with one special exception. The average rate of increase in the receipts in 1903 over 1902 was in this group 7.1 per cent.; in the second group, including companies over $500,000, it was 10.7 per cent.; in companies over $100,000 it was 16.5 per cent.; in companies over $50,000 the increase was 9.5 per cent., and in the fifth group of companies, over $25,000, it was 14.4 per cent. The general average increase for 1903 over 1902 was 8.5 per cent. This is certainly a healthy rate of increase and is, we think, somewhat contrary to the general supposition that there had not been much gain during the last year. The figures of the United States Census Office showed that the gross receipts of all the street railway companies for 1902 were nearly $248,000,000. If we apply the rate of 8½ per cent. increase to this, the gross earnings for 1903 for the street railways of America would reach the splendid sum of not far short of $270,000,000.

Such figures as the above are certainly encouraging. There seems to be no limit, in fact, to the expansibility of the street railway industry under the régime of electricity; and as the years go by it will be very interesting to trace the effect of electricity in increasing the traffic of the steam railroads to which it is applied. It would appear, from time to time, that other modes of traction, like the automobile, for instance, or the bicycle, might have some effect on street railway traffic; and we are not yet very far away from the time when some street railway managers thought they were going to lose all their income because so many people had taken to riding bicycles to and from business. The figures of street railway traffic, in fact, certainly keep pace with the growth in population quite steadily, and appear to have a further rate of development of their own, depending very largely upon the increase of facilities. The figures in New York City bring out such an idea and confirm it, especially as soon as the benefits of electricity are thrown into the scale. In 1884 the street car passenger traffic of New York City was barely 185,000,000 passengers, and in 1894 it was only a little over 245,000,000; but it had jumped at the beginning of this year to 612,000,000. There can be no question of the fact that the extension of electrical facilities had a great deal to do with the last enormous stride. Just at present the rate seems to have fallen off a little bit, but this is due again to the fact that the elevated railroads by the adoption of electricity have once more come up to the proper standard of efficiency and competition, so that their figures of traffic which in 1889 showed only 174,000,000 passengers, or almost exactly what they were eleven years before in 1888, had jumped in 1903, after the adoption of electricity, to 246,000,000. Thus, whereas on the elevated roads in the period from 1893 up to 1899 there was actually a steady decrease in traffic, since 1900 and with the employment of electric traction there has been a tremendous rebound, so that the increase on the system in 1904 was 14.51 per cent.

The inference from all these figures is that the opening up of the New York electric underground system this year, while it may again check temporarily the rate of increase of the existing systems, will be found very quickly to develop its own traffic and to yield a good return upon the investment. This will in turn foreshadow the possibilities bound up in the adoption of electricity for the suburban traffic of the New York Central Railroad, where we believe agreeable surprises await the Vanderbilt management in the unsuspected rapidity of development of the suburban region beyond the Harlem River.

Central Station Management.

Elsewhere we print in full the excellent paper read at the recent Boston National Electric Light Convention by Mr. Frank W. Freuauff on the subject of central station accounting. One matter which the paper brings forward is, however, much broader than the subject of mere routine office accounting, namely, that of analyses of cost, whereby for each class of service the fixed and several variable costs are segregated. The central station industry has now reached the stage when it calls for the same refinements in details as to costs as prevail in the great manufacturing industries, and the sooner the situation is realized by managements the better will it be for their personal welfare and for the interests of their plants. In workshops the system of accounting for each item in the cost of a product from the crude material to the finished ware delivered to the distributor dates back a quarter of a century, and has revolutionized manufacturing organization. In the early stages the system was viewed with suspicion by the owner or manager who had been accustomed to the old methods, and was content to rely on general results without endeavoring to isolate and take account of all the factors making toward success or failure. Such as these have all had either eventually to surrender their prejudices or step aside to make place for the more progressive.

A similar situation is rapidly confronting all central station men, and those who do not get into line will find themselves dispossessed by others who realize the oportunity that awaits men who can apply to the central station business the principles that now guide the conduct of other branches of production. From one standpoint, the fact that central stations operate under franchises that exclude competition has not been altogether without its disadvantage, in that there has been no incentive to watch competitors and emulate their successful measures and guard against falling into their errors. Doubtless to this situation is largely due the fact that but a small percentage of the electric lighting stations of this country are on a good dividend-paying basis. In the succeeding issue we shall reprint another Electric Light Convention paper dealing with a correlated question—that of segregating distribution losses, in order that the matter of their reduction may be intelligently dealt with. We venture to say that there is scarcely a central station in the United States now on a non-paying basis that could not round the corner by following intelligently the indications of these two papers, united with systematic solicitation of new business; and as the two investigations would probably point to the possibility of considerable and even large reductions in rates for each successive profitable increase in business, there would be heart in the work.

The Second German-American Cable.

The completion, last week, of the second German cable, connecting Germany with America, is in line with the recent German activities in colonial and ex-territorial development, to which we referred last week, in noticing the proposed German cables in the East. Modern national competition is for trade supremacy. In the seventeenth century, colonies were sought by monarchies for dominion. In the twentieth century colonies are valued only as trade supporters. A colonist is not only likely to make a consumer of home manufactures, but he is also likely to spread about and advertise home manufactures to his neighbors. The nations competed for land in past days. They now compete for business. The establishment of colonies for business is a business in itself. It calls for coaling stations, docks and a huge accessory government mechanism. Moreover, the establishment of colonies gives hostage both to peace and to war. To peace, because order must be kept in the colonies, and the national honor is involved in the colonial government. To war, because in case of hostilities, colonial possessions become most vulnerable. In practice, the maintenance of communication with colonies is vital to their preservation in event of war. At present, the only safe way of preserving communication abroad is by means of a continuous network of submarine cables. Until quite recently, the cable system of the world was almost wholly British. This supremacy beneath the seas has been a strong military weapon. In peace, cables belong to all nations alike. There is no preferential tariff in cable rates. In war, cables belong to the governments where they land, unless captured or removed. America has established her own cables with her Pacific islands. France has her own cables to African possessions, as well as to the American continent. Germany has established her own cables to America, and now seeks to extend them elsewhere. It is probably only a question of time when she will lay cables to her African possessions, her eastern Asian possessions, and to South America. In one sense these cable expansions make for peace, since the investment associated with them is hazarded in war, and makes the advent of war more ominous and less easy.

Power Transmission and Irrigation.

The Institute meeting at Chicago next week, to discuss power transmission, promises to be quite interesting. It has been organized by the Transmission Committee and a number of important topics are to be taken up, details of which were given in these pages. Incidentally, as the Republican National Convention will be in session at the same time, rates of fare are made easy and the engineers can learn a good deal from the politicians about the smooth-running of machinery.

The great art and industry of transmission by electricity that has sprung up and developed in recent years is worthy of this special attention and will certainly take on greater importance from year to year. We are very far from having yet exhausted in this country the possibilities of the great and small water powers upon which primarily the new art is based, and the diligent prospecting of the last five years should soon bear fruit. It is true that in many of our large central station systems and minor aggregates of circuit the transmission part of the problem is by no means the smallest, but the subject essentially is thought of from the standpoint of reclaiming waste hydraulic power.

In this connection we believe that in various sections of the country power transmission and irrigation are destined to become very closely related, so that we may see many companies playing the dual part just as in the lighting field so many supply both electricity and gas. We note, by the way, some striking figures with regard to irrigation just issued by the United States Bureau of the Census. It appears that in 1902 there were no fewer than 134,036 irrigated farms in the United States, having a total acreage of 9,487,077. Every acre thus irrigated is an increase of the wealth of the country. It takes about twenty inches of rainfall for the production of the crops, and irrigation is necessary in all sections where this amount of rainfall cannot be depended upon. The area increased from 1899 to 1902 nearly 22 per cent. The cost of constructing irrigating systems has amounted to $93,320,452, an average of $9.84 per acre, and the length of main ditches of irrigating trenches is 59,242 miles. The greatest irrigating States are California, Colorado and Montana. California has 1,708,720 acres under irrigation; Colorado, 1,754,761 acres, and Montana 1,140,644 acres. These are figures applying to the arid regions alone. The Mississippi tributaries are drawn upon more heavily for this purpose than any other streams in the country. The systems receiving water from these tributaries have a length of 20,064 miles. It stands to reason that a great deal of the old and new irrigation work must depend upon water received from much higher levels; and in almost every instance there should be a distinct opportunity for utilizing the head in apparatus for light and power, especially with proper systems of water storage.

THE BEAR RIVER POWER PLANT.

Transmission plants are now such commonplaces of engineering that the addition of another to the rapidly lengthening list is seldom an item of essential interest. The plant we describe in this issue, however, is, we believe, unique in that it was installed with the deliberate intention of utilizing the surplus water of an irrigation system during the season of high water. There are various power plants which utilize the artificial falls of a ditch system, put in merely to distribute the water to advantage, but so far as we recollect this is the only instance in which a plant uses unstored surplus and shuts down during a short dry season. Of course such a plan would ordinarily be infeasible, or would be worked only under conditions which permitted extensive use of an auxiliary steam plant. Here, however, the Bear River plant is itself an auxiliary to five other hydraulic plants, together amply capable of delivering all the power needed during the low-load season. It is a water power auxiliary to help out during the long annual peak. There are three steam auxiliaries on the Salt Lake City system, but water being cheaper than steam can be used to great advantage while it is available. The starting of the Bear River plant makes the sixth water power plant of the system.

Salt Lake City is situated in an ancient basin with no near hydraulic powers of any considerable size, and in fact no large powers within a very long radius. Nevertheless, by persistent enterprise enough power has been developed in scattered plants of moderate size to meet most of the local requirements. The six hydraulic and three steam plants are operated in parallel on the low-tension side, and from all accounts pull together with the utmost harmony, thanks to the somewhat flexible connections supplied by the long lines. The whole system is a fine example of utilization of the facilities afforded by Nature in a somewhat ungenerous mood. Hydraulically the novel feature of the plant is the supply of water for the turbines from a huge inverted syphon connecting two main irrigating canals separated by the Bear River bed. This syphon is in part of redwood stave pipe, to which the steel pressure pipes are connected, and by its use water for the plant can be drawn from either canal, or during the irrigation season water can be transferred from one canal to the other. The transmission line is worked at 40,000 volts and is 82 miles long, delivering the output of a pair of 750-kw, three-phase generators. A word may be said here as to the insulators. For these high pressures there is little uniformity of practice, but in this instance massive brown porcelain insulators were chosen and these were individually tested at 120,000 volts before being accepted. A factor of safety was thus secured which should prove sufficient for all ordinary and most extraordinary contingencies. The whole question of high-tension insulators needs overhauling, and until the art is much further advanced than at present, this plan of individual testing, laborious as it is, has much to commend it.

INFLUENCE OF THE LINE ON THE PARALLEL OPERATION OF SYNCHRONOUS MOTORS.

A single synchronous generator on an alternating-current system takes electrical charge of the system in its own way. The moment that another one is added, however, either as a generator or as a motor, there is always a chance for their quarreling and getting out of step. In a perfectly steady régime two synchronous generators running in parallel do not exchange power, and run at the definite uniform phase difference which corresponds to this condition. The moment that a disturbance occurs, either by the pulsation of the prime-mover of one or by some sudden change in load acting dissymmetrically on the two, a change in relative phase is set up whereby a local current is produced between the two generators. The power components of the current will produce torques in the machines, drawing the machines together. By mechanical inertia the two machines will tend not merely to come back to equivalent cophase, but also to swing beyond. If no damping forces were at work, the mutual oscillations about the cophase position would continue indefinitely. Resistance in their local circuit and conductance in magnetically associated circuits, tend to absorb the swing energy from the system and bring the machines into steady cophase (or equivalent cophase for difference of generated e.m.f.).

If then oscillations persist, there must be a persisting periodic source of swing. This source may be either mechanical or electromagnetic. If mechanical, the prime-movers or engines driving the machines pulsate rhythmically, either by the hunting of their governors, or by the periodic fluctuations of driving torque. If the source of disturbance is not mechanical it may be due to hysteresis in the magnetic circuits of the machines. A lag in the magnetic flux behind the m.m.f. of the armatures' magnetic circuits may give rise, under favorable circumstances, to swinging forces, or negative damping, so that the machines will not come into cophase, but will swing apart until the magnitude of the damping actions evoked by the swing balances the disturbing forces; or even, in the worst cases, until the machines swing themselves out of step. The frequency of such free electromagnetic oscillations is independent of the governors of the driving engines, and depends only upon the moments of inertia of the rotors and upon the constants of the local electrical circuit. On the other hand, when the oscillations are of mechanical origin, the period is set by the mechanics of the governing systems and is only affected in subsidiary degree by the electric circuit.

When the swinging is of electromagnetic origin, the magnitude of the restoring forces depends both upon the magnitude and upon the angle of the impedance in the circuit connecting the two armatures. If the impedance is large, either by reason of large resistance or of large reactance, the restoring forces will be small. If the impedance in the circuit is small, the restoring current will be relatively powerful, but the effective component will be the e.m.f. component. Cases may occur in which the resistance of the circuit, as affected by the transmission line, may materially influence the pendulum action, so that the same pair of alternators which would only swing through an electric amplitude of, say, 20 amperes, when operating in parallel side by side, might swing through an electric amplitude of 200 amperes when operating in parallel with the impedance of a transmission line between them. The interesting papers printed in the *Transactions* of the Italian Association of Electrical Engineers, as referred to on page 1155 of this issue, bear upon this interesting condition. The elimination of the danger of excessive electromagnetic pendulum action lies in the design of alternators of insufficient armature reaction and hysteretic lag to overcome the damping forces under any conditions of excitation and line impedance.

International Electrical Congress.

Acceptances of membership in the International Electrical Congress, to be held September 12-17 in St. Louis, now number over 1,700, and more than 160 specially invited papers are promised. One thousand certificates of membership have been issued to those who have become members by sending in their subscriptions and about 100 more certificates are about to be issued.

Efforts are being made to secure the MSS. of as many of the 160 papers as possible by the first of July, in order to have them printed in advance for distribution among the Congress members at St. Louis.

The programmes scheduled for Sections D and E are given below. The similar programmes of Sections A, B and C have appeared in preceding issues.

All communications concerning the Congress should be addressed to the general secretary, Dr. A. E. Kennelly, Harvard University, Cambridge, Mass.

SECTION D—ELECTRIC POWER TRANSMISSION.

Chairman, Mr. Charles F. Scott; secretary, Dr. Louis Bell.

India Rubber in the United States.

It is stated that imports of india rubber into the United States in the fiscal year about to end will exceed by far those of any earlier year, and will amount to over $40,000,000 in value. The demand for this article of exclusively foreign production for use in manufacturing has increased very rapidly in recent years, and the imports in the present fiscal year, as shown by the Department of Commerce and Labor through its Bureau of Statistics, will amount to about 60,000,000 pounds, valued, as already indicated, at fully $40,000,000. This rapid increase is apparently due, in a large degree, to the increasing use of this material for insulation as well as for tires of electric vehicles and automobiles of various classes, though in other lines of manufacture the demand is also very great.

The rapid growth in the use of this article of manufacture in the United States is illustrated in the fact that the total value of india rubber and gutta-percha imported in 1870 was less than $3,500,000; in 1880, $9,500,000; in 1890, $15,000,000; in 1900, $31,000,000, and in 1904 will be fully $40,000,000. The increase in quantity has not been so rapid as the increase in value, owing to the fact that prices have advanced materially by reason of the greatly increased demand of the various manufacturing sections of the world, especially the United States.

In 1880 the quantity of rubber imported into the United States amounted to 17,000,000 pounds, valued at $9,500,000, making the average price about 55 cents per pound. In 1890 the quantity imported was 34,000,000 pounds valued at $15,000,000, or slightly less than 50 cents per pound. In 1900 the quantity imported was 49,000,000 pounds valued at $31,000,000, or about 63 cents per pound; while in 1904 the record of the ten months for which figures are now available shows an average value for rubber imported of 68 cents per pound. In addition to this, however, large quantities of material utilized in conjunction with india rubber are now imported.

Importations of "gutta-joolatong," a product of India, which is used in certain industries as a substitute for india rubber, now average more than a million pounds a month, while importations of old and scrap india rubber to be remanufactured amounted to over fifteen million pounds in the ten months of the fiscal year for which a record is now at hand. These importations of old and scrap rubber for remanufacture and of gutta-joolatong as a substitute in certain lines of work are comparatively new and have only been reported by the Bureau of Statistics as a separate item during a very recent period.

Bear River Power Plant and Utah Transmission Systems—I.

THROUGHOUT all sections of the West the development of electric power from mountain streams goes hand in hand with great irrigation enterprises; and in many cases, especially in Colorado, Utah and California, the tail race of a hydroelectric plant is the headworks of an irrigation system supplying thousands of acres of rich soil with water through extensive canals. Perhaps none of these combinations of power generation and irrigation is more interesting than that recently put in operation by the Utah Sugar Company on the Bear River in Northern Utah, and a noteworthy fact in connection with it is that the usual conditions are reversed, inasmuch as the irrigation interests in this instance have the prior right to the water and electric power is developed only when there is a surplus of water over the needs of the lands below. In other words, electricity is produced as a by-product. The conditions are as follows:

Some 20 years ago the present hydraulic development of the Bear River was made. It consisted in building a diverting dam at the upper end of the Bear River Canyon. This dam diverts water at each side of the river into separate canal systems. The two canals, one on the west bank and one on the east bank of the river, carry the water for a distance of two miles down the canyon through a series of tunnels, flumes and masonry-supported ditches. They emerge at the lower end of the canyon at a height of 115 ft. above the river and about 1,000 ft. apart. From that point the canals diverge, each dividing a little farther on into branches and laterals, thus irrigating several thousand acres of land. These canals are now controlled by the Utah Sugar Company, which operates a beet sugar factory supplied from the large sugar beet farms of the locality.

Although for some time aware of the possibilities on this river, the company had not taken steps to develop power because it had no market. With the rapid growth of Salt Lake City, however, in recent years, there has come a greater demand on the plants of the Utah Light & Railway Company, so the latter was glad to enter into a contract for the entire output of the new station. The development of the power does not lessen the quantity of water available for irrigation, because only the surplus water is used at the station. The canals below the canyon can carry the entire flow of the river only during the period of extreme low water, which lasts but a few weeks in August and September. During the remainder of the year there is more water than is needed for irrigation purposes, and it is this surplus water which is used to generate electric power. The shutting down of the plant during the few weeks in summer comes at a time when the power can best be spared in Salt Lake City, as the lighting and power loads are the lightest at that season, and can easily be carried by the other plants of the system.

The power house is situated on the east bank of the river just at the lower mouth of the Bear River Canyon, and at a point about four miles north of Collinston, Utah. Here a unique plan has been adopted to utilize the water from either canal, which consists in connecting the canals by an inverted syphon and taking out the water for the turbines at the lowest point. The general arrangement of the syphon and power house is shown in the plan and elevation in Fig. 4, and it may also be observed in the illustrations, Figs. 1 and 2.

FIG. 1.—VIEW OF POWER HOUSE AND SIPHON SHOWING EAST INTAKE TO SIPHON PIPE.

The syphon has an inside diameter of 8 ft. and is built of California redwood, the Excelsior Wooden Pipe Company, of San Francisco, having the contract for the work. Each pipe is connected with its respective canal by means of a concrete turnout, which has been carefully designed to prevent loss of head from water eddies, and before entering the pipe the water passes through an iron screen and large wooden gate, which is raised and lowered by means of hand wheel screens from a platform above, as shown in Fig. 3. Fig. 5 is a view of the west canal and inlet.

The pressure pipe on the east bank is 322 ft. long and is laid at an angle of 17° to the horizontal, while the west pipe is 195 ft. long and is laid at an angle of 29°. At the lower ends of the pipes and connecting with the horizontal part of the syphon are specially-constructed, steel-riveted elbows, securely anchored on converter peers. That on the west bank is shown in Fig. 6. Between these elbows is 418 ft. of straight pipe, the west portion crossing the river on a 225-ft. steel three-span bridge (Fig. 2) resting on concrete and stone piers. Opposite the power house, placed 70 ft. apart, are two steel sections, 15 ft. long, from which steel penstocks, 66 in. in diameter, lead to the turbines in the power house. Figs. 5, 6 and

FIG. 2.—POWER HOUSE AND SIPHON.

7 illustrate details of the wooden pipe and also the method of building it. Since these photographs were taken the pressure pipes have been covered with earth and the horizontal portions are protected from the weather by a wooden sheathing.

By means of this arrangement of pipes water for the turbines may be drawn from either canal, or during the irrigation season, if either canal should break through a retaining wall in the canyon, as sometimes happens, the portion of the canal below the canyon can be supplied from the other canal through the 8-ft. syphon, and thus preserve the crops in the valley until the damaged canal is repaired. The bottoms of the two canals are on the same level, but it is estimated that a difference of head of one foot will produce a flow through the pipe of about 320 cu. ft. per second. Thus, if the west canal be filled to a depth of six ft., and the water in the east canal

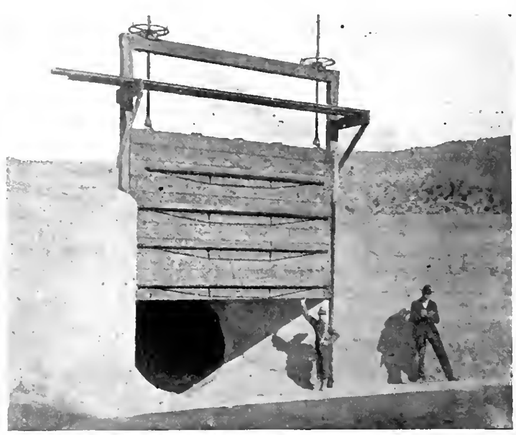

FIG. 3.—ENTRANCE TO EAST INTAKE AND GATE.

stands at a depth of 5 ft., there should be just enough water passed through the syphon to supply all the water which the east canal will carry at 5 ft. depth.

POWER HOUSE.

The power house is substantially built of brick on concrete foundations carried down to bed rock. The roof is supported by timber trusses and consists of standing-seam tin roofing laid on 2-x-6-in. roof boards, which are nailed to 4-x-12-in. purlins. The building is 100 ft. long and 60 ft. wide; 40 ft. from the north wall is a row

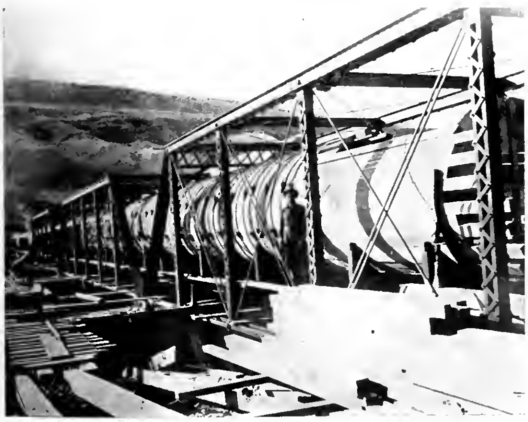

FIG. 7.—BRIDGE AND PIPE.

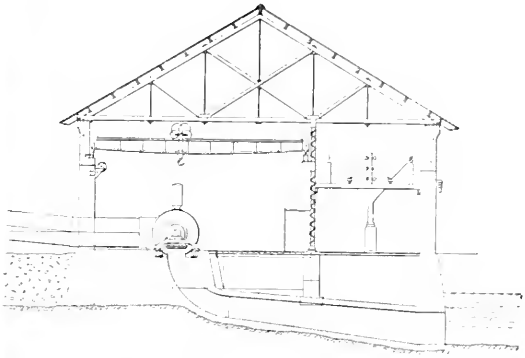

FIG. 8.—CROSS-SECTION OF POWER HOUSE.

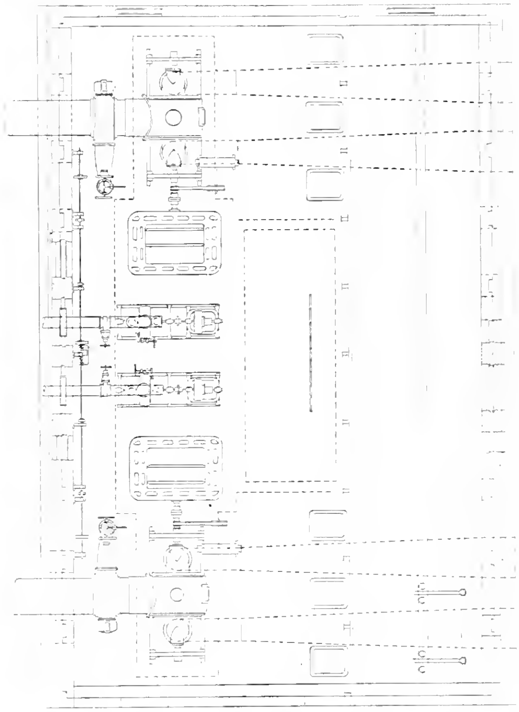

FIG. 9.—PLAN OF POWER HOUSE.

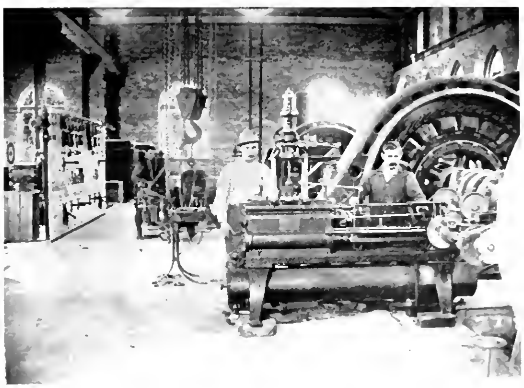

FIG. 10.—VIEW OF INTERIOR OF BEAR RIVER POWER PLANT.

BEAR RIVER POWER PLANT AND TRANSMISSION SYSTEMS.

of steel columns dividing the building into two portions. In the larger portion, which is served by a 20-ton Whiting crane, are located the turbine, generators and switchboard, while the other space is given up to transformers and high-tension switching apparatus. Figs. 8 and 9 show respectively the cross-section and plan of the power station. The building has no basement except under the switchboard. All low-tension wires and cables are carried under the concrete floor in clay conduits.

The hydraulic equipment consists of two 1,400-hp, double-discharge Leffel turbines, each mounted at the end of a 66-in. steel inlet pipe. Each turbine is connected by means of a rigid shaft to a 750-kw Westinghouse revolving-field, 2,300-volt, three-phase alternator. Governing is accomplished by Lombard governors, and levers are also provided for hand regulation. Each of the inlet pipes is provided with a Rensselaer gate valve located just inside the power house so as to be in reach of the 20-ton crane. These valves are among the largest ever made, weighing 17 tons each. They are operated by belting from a 2-in. shaft mounted on the north wall and driven by an electric motor.

Exciting current for the alternators is supplied by generators separately driven by small Leffel turbines, for which water is brought through a 24-in. pipe directly from the large syphon pipe. This pipe branches outside the building into two 18-in. pipes, which supply the turbines. The exciters are thus driven independently of the large generators, and better regulation and greater reliabiility are, therefore, afforded. Figs. 10 and 11 are views of the interior of the power house, showing the large units and switchboard.

The discharge water from the turbines is carried by means of four draft tubes, each leading down with a long 90-degree vertical bend, to a flaring concrete tunnel under the power house floor. These tunnels all terminate in a common tail race and are so proportioned that the water is brought almost to rest before being discharged, so that as much as possible of its energy is utilized. The draft tubes of the exciter turbines discharge into the two inside tunnels.

The nine-panel marble switchboard which receives the 2,300-volt current from the generators has mounted upon it the necessary oil switches and indicating and recording instruments. Three oil-insulated transformers raise the voltage from 2,300 to 40,000 volts. These transformers are set 10 ft. apart and each is exactly opposite one of the 10 windows in the south side of the power house. After leaving the high-tension side of its transformers, each wire of the three-phase circuit passes, without lateral deviation, successively to a static interrupter, a high-tension switch of special design, a low-equivalent lighting arrester, and finally out of the window through a long glass bushing. This window consists of two sheets of heavy plate glass six inches apart, with holes in the centers for support of the bushing. All electrical apparatus in the power house is of Westinghouse manufacture. The transmission features of the plant will be considered in a concluding article.

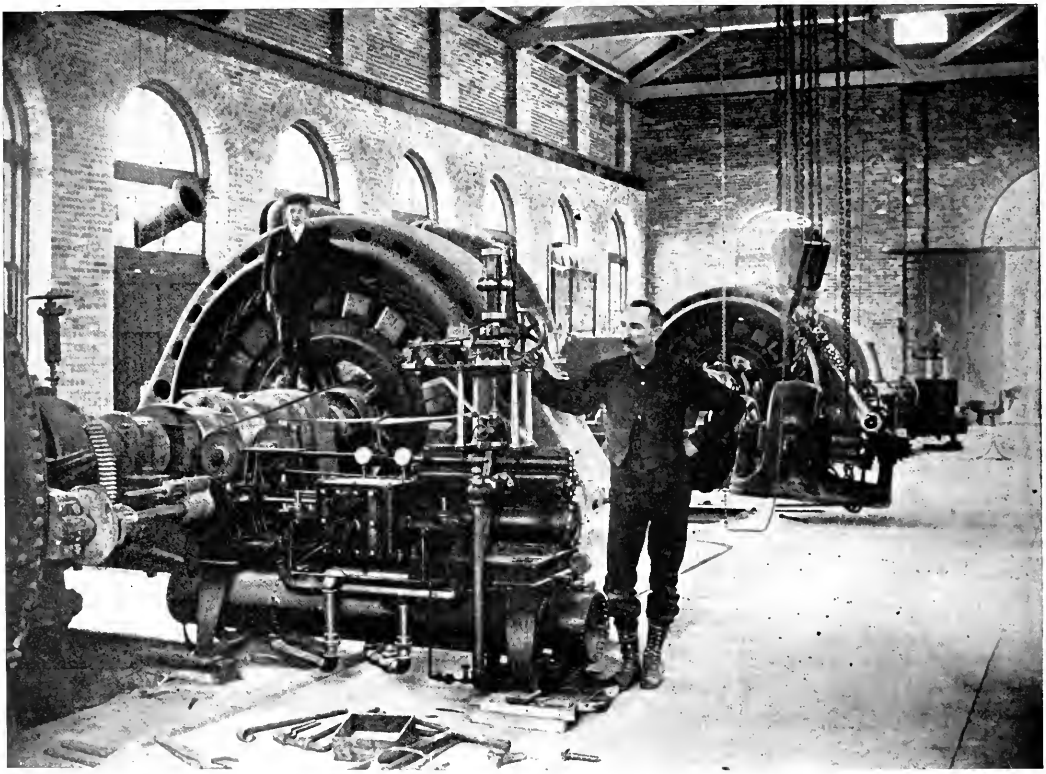

Fig. 11.—View of Interior of Bear River Power House.

Wireless Telegraphy on Russian Ships.

A St. Petersburg dispatch states that the admiralty has installed Siemens & Halske wireless telegraph apparatus on five battleships and the cruisers *Aurora* and *Dmitri Donskoi*. All of the ships that are being fitted out on the Baltic Sea are, it is stated, also being equipped in a similar manner. The Russians appear to have changed their attitude toward wireless telegraphy, since it is but a few weeks ago that a ukase was promulgated against the use of it by neutrals within the zone of hostilities. The operation of wireless systems by the contending forces, and by newspaper correspondents, will no doubt make things interesting, and there will be a clash of forces in the air as well as at sea and on land.

Geysers by Searchlight.

A powerful battleship searchlight has been put in operation in Upper Geyser Basin, at the Yellowstone National Park, to show the working of the geyser at night. The effect, it is said, is marvelously beautiful and hereafter the searchlight illuminations of the active geysers will be a feature in the National Park.

Influence of the Line on the Parallel Operation of. Synchronous Motors.

The Italian Association of Electrical Engineers has printed in its *Transactions* two interesting papers on the influence of the line on the parallel operation of synchronous motors, one by Signor Rebora and the second by Signor Guido Semenza. We give below abstracts of these papers.

Signor Rebora, in introducing his paper, says that it is generally believed that the distance between power houses is not a factor in the satisfactory operation in parallel of alternators, and the object of his paper is to give the result of experiments which will warn electrical engineers to be at least cautious in this matter.

Referring to Fig. 1, *A* is a new power house, built to be operated in parallel with a power house, *B*, 11 miles distant. *A* has three

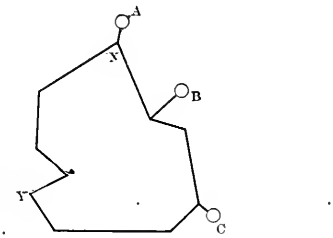

FIG. 1.

three-phase units, of 500 hp each, 360 r.p.m., 6,000 volts, 48 cycles, driven by Pelton wheels. The excitation is supplied by two special groups of turbine dynamos. *B* has three three-phase units of 250 hp each, 480 r.p.m., 6,000 volts, 48 cycles, driven by Pelton wheels. An exciter is belted to each generator.

The line has a total developed length of 50 miles and feeds lamps, induction motors and two 100-hp synchronous motors at *C*. All the generators, as well as the synchronous motors, are of the same type (revolving field, laminated poles, open slots), and their characteristics (saturation curve and short-circuit current) were found to be quite similar. When the new power house, *A*, was ready for operation it was attempted to run the generators of *A* in parallel with the generators of *B*, but in vain. *B* was then cut out, and current was sent from *A* to *C*, but it was impossible to operate the synchronous motors there, though they had been working satisfactorily when commanded by the generators of *B*. Lamps and asynchronous motors were not affected at all by the change of the power house. Signor Rebora then started a series of experiments to find out the cause of the trouble.

While the power house of *B* was working on a certain load of lamps and induction motors, he tried to connect to the line one of the generators of *A*, but as soon as the connection was made the main ammeter, the voltmeter and the exciter ammeter (both at *A* and *B*) started to oscillate violently, with a periodicity of 100 throws per minute, as did also at the same frequency the turbine, the governors and the water in the conduits.

He noticed at once that the oscillations originated in the electrical part of the system. He repeated the experiment several times, changing all conditions which could affect the operation, but the result always remained the same, and did not vary when he tried to couple one of the generators of *B* (250-hp) to one of the generators of *A* (500-hp), the latter being started first. Then he connected the machines of *A* and *B* to the line *A, X, B*, alone—at no load—and under these conditions the generators kept in step. Subsequently he tried to run one of the motors of *A* as a synchronous motor; after coupling it (at no load) as a generator, he shut off the water from the turbine and the machine kept on running as a synchronous motor operated by *B*. However, he was not able to reverse the test, viz.: to run a machine of *B* as a synchronous motor operated by *A*. The coupling of *B* in parallel with *A* as a generator at no load was easily done, but it was sufficient to touch the hand wheel of the turbine driving *B* to start at once the oscillating motion.

Signor Rebora gives an account of a series of schemes that he used in order to run *A* and *B* in parallel, but every one of them failed. After systematically studying and eliminating every reasonable cause of the phenomenon, attention was directed to the influence of the line.

The three conductors which constitute the simple three-phase line in question are supported on wooden poles at the vertices of an equilateral triangle, having a side of 10 in. The following tables give the lengths, resistance and reactance of the different stretches of the line. The capacity is negligible:

	Kms.	Resistance per Wire in Ohms.	Reactance per Wire in Ohms.
A X Y C.	45.00	25.55	13.58
A X B.	18.100	15.45	5.67
A X B C.	31.500	22.75	9.75
B C.	13.400	7.3	4.10
B X Y C.	50.820	37.70	15.75

The configuration of the line suggested an interesting test. First, the motors in *C* were connected directly to *B* through the line *B C* only, and their operation was satisfactory and stable. Then the stretch *B C* was interrupted and current to *C* passed through the line *B X Y C;* the operation became impossible and the pendulum motion appeared. The latter test differed from the former in the length of line only. In the first case the resistance per wire was 7.3 ohms and the reactance 4.10 ohms; in the second the resistance was 37.7 ohms and the reactance 15.75 ohms. This made plain that the regular operation of generator and motor depended on the length of the line between them. A remarkable feature was that even during the pendular vibrations the machines did not fall out of phase.

Signor Rebora repeated his experiments in another plant with very large machines. A sketch of the line is given in Fig. 2. It was

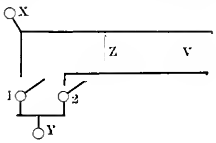

FIG. 2.

possible to use three lengths of line between the generator *X* and the synchronous motor *Y*, viz.: *X Y, X Z Y, X V Y*. The resistances per wire were as follows:

	Kms.	Resistance per Wire in Ohms.
X Y.	12	8
X Z Y.	48	58
X V Y.	84	108

The following experiments were made: (1) Switch 1 was closed (12 km. of line and 8 ohms) and the running in parallel was satisfactory. (2) The current was taken through *X V Y* (108 ohms and 84 km.) and the characteristic pendular motion made its appearance. With the switches 1 and 2 the "hunting" would be started and stopped at pleasure.

When the machine *Y* was operated through the line *X V Y*, the closing of switch 1 was sufficient to damp and eliminate the oscillations, while by closing 2 and opening 1 the vibrations increased up to their full amplitude. In this test, however, it was found that hunting could be stopped by a certain value of excitation: but a further lengthening of the line would probably reproduce the phenomenon, steadily, at any excitation.

Naturally this question presented itself: What influence had respectively the self-induction and the resistance of the line? In order to easier carry out experiments, Signor Rebora made his test on two alternators in the same power house connected through an artificial resistance, inductive and non-inductive, and gives the following results of his observations: Alternators and synchronous motors assume at no load or full load a pendular motion when the resistance of the line between them reaches a certain value. Experimentally, it is difficult to find this exact value, but some limits are obtainable between which the operation becomes unsteady. The self-induction of the line has no important effect on the machines. The phenomenon is affected by the magnetic and mechanical elements of the machines, such as the construction of poles (laminated or solid) the degree of saturation, the resistance and reactance of the windings and the inertia of the rotating part.

The experiments started by Signor Rebora have been continued by Signor Semenza, who gave an account of his work in a paper presented in December, 1903, before the Associazione Elettrotecnica Italiana.

Signor Semenza has carried out two series of experiments. In the first he used two alternators of 300 kw, 42 cycles, 420 r.p.m., 3,550 volts in the same power house, driven by direct-current motors fed by a storage battery. This was an almost ideal condition of operation and the results of the test correspond exactly to Signor Rebora's observations, as follows:

(1) The resistance of the circuit connecting the two alternators has the effect of producing under some conditions a pendular motion. (2) The amplitude and the period of the vibrations increase with the resistance of the circuit. (3) After a certain limit of the resistance the machines fall out of step. (4) The pendular oscillations have no apparent cause, but appear almost automatically and increase gradually. (5) The phenomenon differs in the case of both machines running as generators from the case of one machine running as generator and the other one as motor.

The second series of tests was carried out on a synchronous motor of 165 kw, 42 cycles, 3,600 volts, 315 r.p.m., connected to the main bus-bars of the plant of Milan, the power of the motor being negligible in comparison with the power of the generators. The results of the experiments were as follows: (1) The amplitude of the oscillations is the greater the farther from the position of $cos\ \phi = 1$ the machine is operated. (2) With the excitation corresponding to $cos\ \phi = 1$ there is no tendency to the pendular motion even with high resistances of the circuit. (3) The reactance of the circuit has decidedly the effect of decreasing the amplitude of the vibrations. (4) In the condition of $cos\ \phi = 1$ the oscillations stop rapidly. (5) The frequency of the oscillations do not seem to have any connection with the stability of the operation.

Mr. Semenza gives the following explanation of the phenomenon: Let us recall the vector diagram of the e.m.f's of two alternators, running in parallel, at no load. If their e.m.f's are the same and the speed of their prime-movers is identical and the regulation is perfect, the diagram is reduced to one straight line. But these ideal conditions are never reached in practical operation, and the diagram is as in Fig. 3.

The two e.m.f's, $O\,E_1$, $O\,E_2$, form an angle, α, and a difference of potential, E_1, E_2, exists at the terminals of the circuit formed by

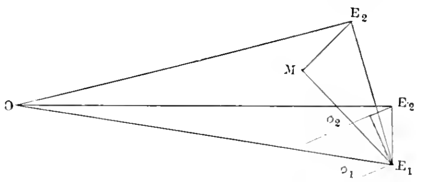

FIG. 3.

the two armatures of the alternators and the line connecting them. A current will flow, determined by the impedance of that circuit. If $E_2M = i\,r$ and $M_1E_1 = 2\,\pi\,n\,Li$ (r and L being the resistance and the reactance of the circuit) the current, i, will have the direction E_2M, and the angles ϕ_1 and ϕ_2 will represent the difference of phase between this current, i, and the e.m.f's of the generators. Now, as far as the resistance and the reactance will not change, the triangle, E_1, E_2, M, will remain similar to itself.

If instead of two generators we consider the case of a synchronous motor connected to bus-bars and the power of the motor is negligible in comparison with the power of the generators, the diagram does not change, but $O\,E_1$ represents the voltage at the bars and $O\,E_2$ the e.m.f. of the motor, and r and L include the resistance and reactance of the motor and of the line connecting it to the bars.

The diagram refers either to single-phase or three-phase machines, if in this latter case we assume that $O\,E_1$ and $O\,E_2$ represent the voltages between the terminal of each phase and the center of the star.

It must be remembered that the current given out by generators running in parallel or taken in by synchronous motors varies with the intensity of the current of excitation, as it is shown by the well-known V curves.

In our vectorial diagram the variation of the value of the exciting current is represented by a shortening or lengthening of $O\,E_1$. When $O\,E_1 = O\,E_2$ and the machines run free, the angle between the two e.m.f's is very small and the direction of the current E_2M is very close to the direction of the e.m.f: the resultant e.m.f., E_1, E_2, reaches a value sufficient to generate the necessary current to supply the power for driving the motor, and since $cos\ \phi_2$ is nearly unity, this current is very small.

But when $O\,E_2$ is different from $O\,E_1$ the angle ϕ increases and consequently the armature current also increases, owing to the fact that the triangle, E_1, M, E_2, must remain similar to itself. This current may lag or lead, depending on the excitation. To be more rigorous, it would be necessary to distinguish the position of $cos\ \phi_1 = 1$ from the position of $cos\ \phi_2 = 1$, but practically these positions are so close together that they can be assumed as coinciding. If the impedance of the circuit remains constant, but the ratio between resistance and reactance changes, the triangle will assume a different form.

By increasing the resistance, the angle E_1, E_2, M will decrease and consequently ϕ_2 will increase, while by increasing L ϕ_2 will decrease. This shows that the resistance and the reactance have an opposite action on the internal displacement of phase of the motor, and it may be easily seen that the resistance calls for a more peaked V curve (this curve is plotted with the amperes of excitation as abscissæ and the amperes of the armature as ordinatæ), while the reactance tends to smooth it. By considering the V curve it can be noticed that in the region of low excitation a point can be reached where the curve becomes vertical or bends backward, and this represents a limit of excitation, at which the motor can no longer keep in step, and the corresponding current will be the smaller, the higher the reactance of the circuit and the lower its resistance.

These deductions will be explained much better by looking into the physical side of the phenomenon. Let us consider a three-phase synchronous motor. The current flowing in the stationary armature sets up a traveling field which drags the inductor. If the excitation corresponds to the minimum input of current, the axes of the poles of the inductor coincide with the axes of the armature field. But if we change the amount of the excitation or we accelerate the rotor, the axes of the poles are shifted, a heavier current is allowed to rush in the armature, the armature field is intensified, and a torque is produced tending to bring back the poles to their former position. This is the principle of the running in parallel of alternators. Furthermore, since the intensity of the armature field may be assumed as proportional to the current, and the e.m.f. of the motor is generated by the flux of the rotor, this synchronizing action is $E_2\ i\ cos\ \phi$. This expression actually represents the power required to compensate the losses of the motor, which is explained by the fact that the action of bringing back the rotor to its normal position corresponds to a variation of kinetic energy—that is, corresponding to a positive or negative work done by the motor. The same thing happens in the case of two alternators running in parallel, every relative displacement between them tending to retard the machine which has been accelerating and to accelerate the machine which has been retarding. Of course, there is a limit; there is a certain angle of displacement, after which the synchronizing action decreases. This angle is $E_1\ E_2\ M$, and its tangent is $\frac{2\,\pi\,n\,L}{r}$, which shows again the opposite influence of the resistance and the reactance.

These graphic representations which make so simple the study of the alternating-current phenomena, have generally the fault of neglecting many of the essential elements. In fact, we have assumed the currents as sinusoidal and they are not; we assumed the reactance of the circuit as constant, while it changes with the position of the poles, the amount of the excitation and the value of the armature current; finally, an important element has been neglected, namely, the reaction of the armature.

As to the pendular oscillation on a three-phase synchronous motor, let us assume that the e.m.f. of the motor forms an angle α with the e.m.f. of the bus-bars, and that an external impulse has the effect of increasing the angle α; as we have seen, a torque will be produced tending to retard the rotor. But while the acting torque varies instantaneously with the reciprocal position of rotor and stator, the variation of the speed follows this torque, lagging behind it on account of the inertia of the mass. We have then the sufficient conditions to produce a pendular motion. In the same way the pendulum keeps up its motion, for when the mass has reached the lowest point and the horizontal component of the gravity is reduced to zero the mass maintains the speed acquired in falling.

Then the rotor after receiving an impulse goes back to its normal position and exceeds it, assuming a pendular motion. This motion would be kept up indefinitely if there were no damping actions. Regarding the frequency of oscillations, Blondel gives for it the following formula:

$$F = \frac{p}{2\pi}\sqrt{\frac{2\,E_1\,E_2\,sin\left(a\,r\,cot\,\frac{2\,\pi\,L}{r}\right)cos\,\theta}{2\,\pi\,n\,R\,\sqrt{2\,\pi\,n\,L^2 + r^2}}}$$

Where $2p$ is the number of poles, n the frequency of the current, K the momentum of the rotating part. A similar formula is given by Steinmetz.

The influence which the formula attributes to the resistance and reactance are stated to correspond exactly to the results of the tests made by Mr. Semenza.

Owing to friction, a pendulum does not maintain its motion indefinitely; analogously, the currents produced by the pendular motion of the alternator in all the metallic parts of the machine and the mechanical friction absorb the energy of the oscillations. Therefore, it must be borne in mind that the pendular motion cannot be kept up by simple inertia on account of the strong damping forces, but there is necessary the intervention of another cause to continue the vibrations.

In the experiments related above it was noticed that the pendular motion started with no apparent external reason, and that the vibrations increased in amplitude gradually up to a certain limit. The test of the first series shows that the cause of the phenomenon is to be found in the motor itself. This cause, which has been pointed out recently by Steinmetz, is the reaction of the armature. When the current of the armature is in phase with the e.m.f. of the alternator, it sets up a flux of reaction, the effect of which is comparatively small, due to the fact that when the polar shoes are exactly in front of the coils of the armature the current in these coils is zero. It is known how the reaction increases when the current is lagging or leading. Now, when the motor or the alternator is oscillating, the reaction of the armature will pulsate with the same frequency, the displacement of phase of the currents being variable during the oscillation. But since the flux in the iron is not in step with the m.m.f., but is lagging behind it on account of the molecular friction of the iron, the reaction of the armature will attain its maximum value while the poles are coming back after having made their maximum swing.

If we suppose that the swinging has originated a leading current, the reaction will help the flux of the inductor; and when the poles start backward from the farthest point of the oscillation, the inducing flux will keep on increasing for a little while, thus giving to the rotor an impulse in the same direction in which it is itself changing its speed. A similar result would occur in the case of a pendulum if the soliciting force were increased in the descending period and decreased in the ascending period, in which case the amplitude of the oscillations would tend to increase.

We have then two forces which act oppositely—the impulses due to the reaction of the armature tending to amplify the oscillations, and the damping forces tending to stop them. The phenomenon will naturally assume different forms, depending on the value of the above actions.

When the alternator running in parallel or the synchronous motor is in the condition of minimum current, the difference of phase is very small and the reaction consequently weak; the damping forces overrule and there is no pendular motion.

On the other hand, when the machines are working in the higher part of the V curve, the currents are heavy and considerably out of phase; consequently the intense reaction varies very much in accordance with the pendular displacement, and there will be a tendency to originate a permanent oscillatory motion of such amplitude that the energy of the soliciting impulses is equal to the energy absorbed by the damping forces. If the special conditions of the circuit call for amplitudes exceeding the limit angle of stable running, the machine will fall out of step; under other conditions we will have stable operation or the permanent pendular motion.

Signor Semenza shows how the results of the tests mentioned in the first part of his paper and the other experiments related by Signor Rebora may be easily explained by the above theory on the running in parallel of alternators. He finally puts forward the following general ideas on the phenomenon.

In every case of running in parallel any perturbation in the speed has a tendency to produce the pendular motion. The oscillations are favored and supplied by the pulsations of the reaction of the armature, which pulsations on account of the magnetic hysteresis of the iron act to encourage, while the damping forces which absorb the energy of the oscillations tend to stop forced pulsations.

Every action increasing the reaction of the armature helps to produce the oscillations. The resistance and the reactance of the circuit have a very important effect, and the resistance may cause some serious troubles when the two synchronous machines are connected through a long line. In fact, the resistance of the alternator is generally very low in comparison with its reactance; by introducing in circuit a line with a resistance of the same order of magnitude or even much higher than the reactance, the ratio between these two quantities may fall beyond the limit of regular operation.

These limits depend on the construction of the alternator, and generally in the case of a long line of transmission they are easily reached.

The operation in parallel of power houses situated far apart can no longer be considered as a problem of easy solution, and manufacturers will be required to design special machines to fit particular cases.

Signor Semenza, in conclusion, expressed the hope that a complete theory of the phenomena considered may soon be contributed by an authority in the branch of alternating currents.

Variation of Motor Speed With Variable Line Voltage.

BY J. L. DICKSON.

THE question of variation of motor speed with line voltage is an important one, and it is the purpose of this article to outline in as simple a manner as possible two different methods of investigation.

In Fig. 1 let M represent the armature of a shunt motor, F its field, R the field resistance, S a switch for breaking the circuit, T the mains, and L a lamp bank. The apparatus is to be connected

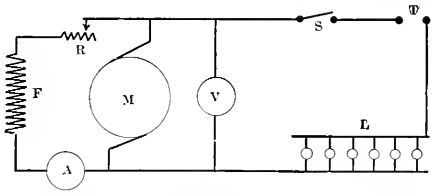

FIG. 1.—CONNECTIONS FOR VARYING CURRENT IN FIELD, VOLTAGE AND SPEED.

up as shown in the diagram, the voltmeter, V, being across the brushes of the machine and the ammeter, A, in the field circuit. The object of the above connections is to vary the current in the field, the voltage across the brushes and the speed of the armature. This is accomplished by means of the lamp bank, L, which regulates the amount of current passing through the entire circuit.

A definite amount of current is allowed to pass through the lamp bank, then the armature is brought up to normal speed by regulating the field resistance, R; the current through the lamp bank is then gradually decreased, step by step, until a sufficiently low reading is obtained, the speed and voltage in each case being noted.

Let us assume that during a certain test readings in Table I were taken:

TABLE I.

Volts Across Brushes.	Armature Speed r.p.m.	Field Amperes.
114	780	1.71
101	720	1.53
96	695	1.45
89	667	1.33
82	640	1.22
66	600	.98
62	585	.92
58	578	.87
55	570	.83
54	566	.80
52	564	.77
49	560	.72
46	558	.68
43	546	.64
36	533	.54
32	520	.47

From these data let us plot the volt-ampere curve (Fig. 2), using volts across brushes as abscissæ and field amperes as ordinates. This curve is found to be a straight line and shows that the voltage across the brushes varies directly with the field amperes.

The above curve can also be obtained as follows: It is seen from Table I that the drop in voltage is 114-32 or 82 volts, and the resistance for the first reading is $R = \dfrac{E}{I} = \dfrac{114}{1.71} = 66$ ohms, while

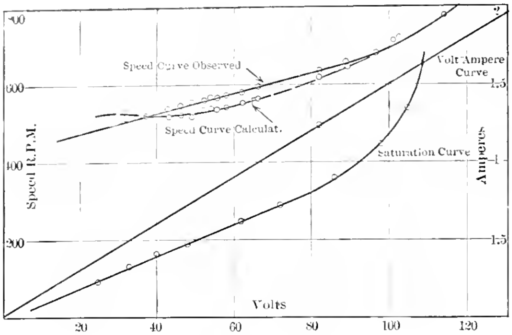

FIG. 2.—VARIATION CURVES.

for the second reading it is $R = \dfrac{101}{1.53} = 66$ ohms. In this manner it is found that the average resistance is 66 ohms; therefore, the current is $I = \dfrac{E}{R} = \dfrac{82}{66} = 1.24$ amp. We then plot 1.24 amp. and 82 volts and connect this point with the origin by a straight line.

Also, from the above readings a speed curve is plotted, using volts across brushes as abscissæ and armature speed as ordinates. This curve shows that these two quantities bear a certain relation to each other, and that as the voltage increases so does the speed, but more gradually and not in a like proportion.

The motor is then to be used as a generator and connected up for a saturation test as shown in Fig. 3, where G represents the armature, F the field, R the field resistance, S a switch for breaking the circuit, L a lamp bank and T the terminals of the generator, G. The

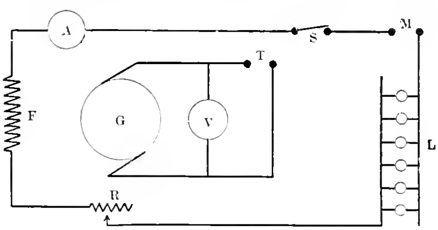

FIG. 3.—CONNECTIONS FOR SATURATION TEST.

field, F, is separately excited from the mains, M, and an ammeter, A, is placed in the circuit as shown. The machine is brought up to speed and the field, F, excited from the mains, M; then the current in the field as read by the ammeter, A, and the voltage across the brushes, taken from the voltmeter, V, are to be noted; the current in the field is then decreased by adjusting the lamp bank and the voltage and amperes again noted. The current is thus decreased until the desired amount is obtained, readings being taken in each case. Suppose for this test the following readings in Table II were noted:

TABLE 2.

Volts Across Brushes.	Armature Speed r.p.m.	Field Amperes.
105	780	1.36
98	780	1.13
86	780	.89
72	780	.72
62	780	.62
48	780	.46
40	780	.36
33	780	.31
25	780	.23

From these readings a saturation curve is plotted (Fig. 2) using volts across brushes as abscissæ and current in field as ordinates. This curve shows that the voltage increases with the current, but not in the same ratio.

If it is desired to obtain the speed curve by calculation, from Table I it is seen that the speed varies with the voltage in the armature, or $S = V_A$ (1) where S = speed in r.p.m. and V_A = volts across armature. Also, the speed varies inversely with the magnetic field, or letting the field be represented in volts generated at speeds 780, 720, etc. (Table I) we have

$$S = \frac{1}{Fv} \qquad (2)$$

where Fv = strength of magnetic field in volts.

Equation (1) is then combined with equation (2) and there results:

$$S = \frac{V_A}{Fv} \qquad (3)$$

The speed for each reading equals $\dfrac{V_A}{Fv}$ multiplied by some constant, K, or

$$S = K \times \frac{V_A}{Fv} \qquad (4)$$

Substituting the first values from Table I we have $780 = K \times \dfrac{114}{114}$, or solving the above equation, $K = 780$. Therefore, the constant is found to be 780. (Fv is taken as 114, because for this reading the strength of magnetic field represented in volts is 114.)

The second values, Table I, are then substituted in formula (4), or

$$S = 780 \times \frac{101}{108} \quad \text{or}$$

$$S = 729 \ r.p.m.$$

The magnetic field, $Fv = 108$, is found from the volt-ampere and saturation curves (Fig. 2). We find 101 volts on the volt-ampere curve, and from this point we go horizontally across to the saturation curve and from this last point we come vertically downward until the abscissæ axis is reached; here the voltage is read and for this case it is found to be 108 volts.

The above method is pursued for finding the magnetic field, Fv, for each case, and substituting in the speed formula we have the values given in Table III:

TABLE 3.

Volts Across Brushes.	Armature Speed r.p.m.
114	780
101	729
96	699
89	664
82	627
66	562
62	550
58	538
55	530
54	533
52	534
49	531
46	533
43	524
36	530
32	531

From these readings another speed curve is plotted as before, which is shown in broken line in Fig. 2, and resembles very closely the previously plotted speed curve. If counter e.m.f. and slight inaccuracy in plotting and reading curves are considered, it is very probable that this latter curve would correspond nearly exactly with the observed one.

The Telescriptograph.

The following rather curious item comes to a New York daily newspaper in a cable dispatch from Brussels of June 11: "M. Malcotti, an Italian engineer resident of this city, has invented an instrument which he calls a telescriptograph, and which will reproduce in print all conversations held over the telephone. He has already secured patents in several European countries and in the United States, where he intends to install his service with the aid of some telephone company. Experiments given in public have demonstrated the wonderful achievements of the young inventor, who claims that his instruments will work without extra wires and apparatus over any ordinary telephone line."

Storage Battery Plate Construction.

By S. H. RABENALT.

WITH reference to the article written in the ELECTRICAL WORLD AND ENGINEER under date of May 21st, by Mr. W. W. Donaldson, on "Storage Battery Plate Construction, with Special Reference to Discharge Characteristics," I take the liberty to take exception to a few statements made.

1. " * * * Provide for good electrical conditions, and the mechanical will take care of themselves." This is hardly a right fundamental principle for the construction of a Planté plate. Is it not just as important that a battery plate retain its original shape, its mechanical structure, during its working period, as it should fill the other requirements of capacity, low-potential drop on high rate discharges, low internal resistance, etc.? Not only should this point not be neglected, but it should be one of the fundamental points to be considered in the construction of Planté, or, in fact, any plates.

One of the chief requirements in station batteries is that the possibilities of short-circuits be eliminated as far as possible. Of necessity, therefore, the plates proper must be rigid; that is, their shape and mechanical structure should not change during the entire life of the battery, no matter what changes in form the active material portions are undergoing.

Most of the Planté designs of the present days comprise ribs and grooves, varying in shape and size, the grooves being designed to hold the active material—electrochemically formed from a part of the ribs. Now, if the plate is to maintain its capacity, the active mass must be retained in the grooves. Experience has taught that the best method of accomplishing this most efficiently is to fill the grooves in the forming process rather tightly, thus not allowing the active mass to become separated from the contact surface by violent gasing resulting from excessive overcharges, which Planté plates are expected to withstand; but where a space is left in the grooves between the layers of active mass on each side, this does occur, and the result is evident.

It is a common thing for Planté positive to "grow" and "buckle," both being most frequently caused by excessive overdischarging and not sufficient charging; this causes an additional formation and volume increase of the active material, this being called "Planté action." The grooves—assumed filled—are unable to accommodate this addition of mass, and the whole active portion (the portion of the grid which contains ribs and grooves) expands. If the expansion on both sides of the plate is balanced, the plate "grows" (expanding force acting in a linear direction); if unbalanced, the plate "buckles" (expanding force changing its direction continually). It is the "buckling" that causes the numerous short-circuits in some types of batteries.

On the other hand, if the grooves are not quite filled with active mass, thus providing space for the "Planté action," the possibilities of growing and buckling are very much decreased, but how about the capacity question? Before benefit is derived from this provision of space, the amount of the active mass may have been reduced considerably, as mentioned above, and the provision prove useless.

It would, therefore, seem advisable to construct a Planté positive of a large number of small "units," comprising the "active portion" of the plate, and to weld these into a solid and rigid frame of antimonial lead. (I do not belong to the class of "cranks" who believe in "always complicating and retarding the proper chemical actions. * * * ") Each section or unit should be joined to the frame at its upper edge only, and be allowed to follow its tendencies, to expand or grow, in three directions, and there should be sufficient space provided that these changes in the individual units may take place without destroying or changing the form or dimensions of the plate as a whole, which fact allows the individual units to be constructed so as to retain the active material.

The writer, who is fortunate in having had an appreciable amount of practical battery experience, considers this type of a Planté positive more nearly the ideal station plate than that described by Mr. Donaldson, in spite of the fact that he condemns the class of "built-up" plates most decidedly. The fact that there are Planté positives in service, whose vertical edges follow a zig-zag line after several months' use, and the shape of the active portions reminds one of a bowl, shows conclusively that there are constructors who "let the mechanical conditions take care of themselves!"

2. "The fundamental requirements for both plates is that their active material must be formed by an electrochemical action. No paste or applied active material should enter into the construction of either plate for stationary high-discharge work." Why? The necessity for a Planté positive, of course, is evident, and the subject has been so thoroughly and on numerous occasions, dealt with, that I consider it superfluous to go into details. But how about the negative?

As far as the writer is aware, there is but one storage battery company in the world that installs batteries having negative plates of the Planté type, and as the number of installations of this kind probably amounts to no more than 1/100 of one per cent. of the total battery installations, it is unreasonable to assume that the use of a Planté negative plate is ideal or even desirable.

The assertion above noted is too general for a detailed discussion. It might be mentioned, however, that batteries installed with Planté negatives, result in exceptionally high c.e.m.f. on charge, and are very susceptible to "treeing."

3. " * * * The plate must not be built up of separate parts." This is another statement to which I take exception. Mr. Donaldson goes on to say that the active material should not be relied on as a conductor of current. Here it seems to me that the author has in mind a certain type of an earlier origin than "the well-known type" whose positive plate is mainly characterized by the peculiarly shaped active units which suggest a series of buttons. In that type it is true the entire current, developed in a unit or button has to travel through a portion of the active material (the periphery of this spiral), the active material being compelled to take the part of a conductor. I admit that in this respect the mentioned type does not comprise the "ideal" Planté plate, but undoubtedly the type in question results in a rigidity which cannot even be dreamed of in connection with the "well-known type."

It is not necessary that the active material of a small unit should play the part of conductor, as it does not in the type described by the writer. Therefore, it is not fair, from a neutral, technical point of view (which I suppose the author has taken), to condemn a class of plate generally because he finds a bad defect in one particular type of this class.

4. It is stated that no other metal save pure lead should be used. There is certainly constant local action between the PbO_2 and Pb of the grid, this being an increased function of the contact area, but in my opinion the increase in local action caused by a moderate percentage of antimony in the grid (the only metal alloyed with lead for battery use) is, if other conditions are kept the same, inappreciable.

5. I will, of course, not deny the fact that rolled lead is denser than cast lead, and I also admit that the former offers somewhat more resistance to the oxidizing actions of the current, i. e., Planté action. But to generalize the claim of superiority of one kind of lead over another on that score is not justifiable. And contrary to this assertion, I wish to say that in some respects it may not be best to employ rolled lead in battery constructions, for the plates will very frequently be subjected to excessive overcharges, more seldom overdischarges. This condition will develop a very pronounced tendency, caused by violent gasing, to expel the active mass, emptying the grid and decreasing the capacity in proportion. If very dense rolled lead has been employed in the construction, the contact surface will be very smooth; and owing to the greater resisting qualities toward Planté action, will remain smooth, with an extremely thin layer of peroxide and a proportional capacity. Cast lead being more susceptible to Planté actions, will be peroxidized by the repeated charges and discharges to a far greater extent, giving to the positive plates the ability to take and hold a charge, while plates of rolled, dense lead will be less attacked and will have proportionately less capacity.

In cases where batteries are subjected to very extensive discharges, especially at low rates, and also charged at quite low rates, it would be best to use a very dense lead. The density of cast lead may be greatly varied by varying the pressure under which the casting is done, or by compressing the casting as it solidifies.

6. Some interesting figures are given for percentages of weight of supporting frame to weight of plate proper. As to 15 per cent. for frame construction, it is obvious that "the mechanical conditions take care of themselves." If a plate is to remain in its original shape and not adopt curves similar to an ocean wave, it might be well, perhaps, to increase the above percentage.

It is impossible to give an absolute figure for the amount of lead to be used in the frame construction, as it depends entirely upon the design of the grid. While in some well-constructed types 25 per cent. to 30 per cent. may result in a rigid plate, 40 per cent. to 50 per cent. may prove insufficient in some others, and the "well-known type" has proven conclusively that 15 per cent. is altogether insufficient.

The contact area and thickness of the support (ribs) are, in my estimation, well considered.

7. It is stated that the plate, as a whole, should be as thin as consistent, and should not exceed one-half an inch from face to face. The object of this is not clear to me. It would be very interesting to hear on what basis this assertion is made.

For each individual type such limit can be determined, beyond which the characteristics are commenced to be unfavorably influenced, but hardly for *all* types. I wish to mention the fact that some leading European types exceed a half inch by a good deal. Were those constructors all wrong in their viewpoints?

8. The argument is advanced that the grooves should be tightly filled in order to maintain contact between the grid and the active mass. This argument I condemn most decidedly. The fact that a groove is tightly filled will not prevent the formation of additional peroxide if conditions favor a tendency for it.

If the grooves are so tightly filled that they are unable to accommodate additional mass, the mass will make itself the necessary space. If the frame construction (which encloses the active portions *tight*, not providing for expansion space) is made out of soft lead, the plate will grow and buckle. If the frame construction is made out of antimonial lead (with a comparatively high percentage of antimony) the plate will very often crack and break.

It is further stated that the negative plate should be integral and of pure lead, alloys to be avoided on account of local action. If local discharges take place in negatives, it is not so much due to the action of alloys, as due to a primary sulphation of the spongy lead. Metallic lead undergoes a slight sulphation in diluted sulphuric acid. Since from a chemical point of view spongy lead and solid lead are one and the same (the difference between the two is solely of physical nature) the spongy lead will, therefore, also undergo a sulphation, only to a much greater extent, for the spongy lead offers the acid more attacking area, being so finely divided. And sulphation of an active mass means discharge.

It is claimed that "local actions due to alloys are the chief cause of capacity loss in many forms of negatives." There is, of course, local action between an alloy of lead and pure lead. But is the local action in a positive not far greater? First, the contact area in a positive is from 10 to 20 times as large as the area in a negative, and the local action takes place in a ratio to the contact area. Second, the intensity of the current being active in the local discharge is far greater between peroxide of lead and lead as between a lead alloy and pure lead, because the former combination gives a much higher e.m.f. than the latter.

The maximum local discharges in a negative (the primary sulphation plus the electrolytic sulphation caused by the alloy) are only a very small portion of the local discharges which take place in the positive plate; therefore, this point can be neglected with good conscience.

Central Station Office Methods and Accounting.

In introducing his paper on the above subject read before the recent Boston Convention of the National Electric Light Association, Mr. Frank W. Frueauff said that the lighting companies throughout the country are all making an effort to increase their sales of current either to present users or new consumers, or by taking on business that was formerly done by isolated plants or other forms of power. These conditions have necessitated a much closer study of costs and receipts and have resulted in a much finer separation of the items entering into the cost of production for any particular class of current or for consumers using service in an unusual way. The usual method of grouping all expenses under the three arbitrary heads of manufacturing, distribution and general expenses and making separation under them for different sub-divisions desired, has only given costs and must therefore be misleading for purposes of figuring for new business to be secured or for analyzing present results in order to know the profitable from the unprofitable business. The plan of apportioning the costs of operation to the class of current made and of separating fixed and variable costs has therefore come to be a necessary part of a company's report of operations, and is now in operation among a number of companies with marked success.

The expenses occasioned in manufacturing and distribution for any one class of current are kept distinct from those incurred in another, so that the actual cost of manufacturing and delivering arc, power or alternating current is known separately. These costs for any one class are also separated to show the costs that are fixed as distinct from those that are variable. For example, station foreman, meter department, shop expenses, etc., are practically a fixed expense; that is, they are an expense resulting from the size and running of an electric business and do not noticeably vary as the business may increase or decrease. Some expenses depend upon the amount of current made and sold; that is, they vary with the output. For example, boiler fuel, firemen, lamp renewals, carbons, and so on. A third class of expenses is made up of those that vary with the number of consumers supplied or number of meters in use. Under this head may be included meter repairs, arc-lamp repairs, service repairs, meter-reading expense, collection and office salaries.

With the cost of current for any class of current separated into these three divisions, it is possible to know just what results are being obtained. One may then know whether or not the output expenses are increasing at a greater rate than the output, and if the expenses proportioned to consumer are increasing faster than the number of consumers. In figuring rates to be made to secure new business this plan of separating costs is particularly valuable. For example, in figuring to take on a long-hour burning consumer you know from the figures of costs that the fixed costs will not be materially increased, nor will the consumer expenses, and that only the output cost will be increased. You may therefore assume that this business can be secured at a very low figure and still show a much larger margin of profit than business that will add to your expenses of capacity or consumers while only showing a small amount of current used.

COMPLAINTS.

The electric companies are now realizing as never before that a satisfied consumer is one of their best assets. To make or hold these satisfied consumers requires constant and careful watching. A department of the business is established where these complaints are received and adjusted. They must be systematically followed up or great dissatisfaction will result. One plan in use is to record all complaints as received, showing the date, name, address, time complaint was received and nature of complaint. From this record typewritten orders in duplicate are made on a 3 x 5 slip, the original being sent to the inspection department immediately and the duplicate being held to insure the return of the original. The order is given to an inspector, who attends to the complaint as carefully as possible. He notes on the order the result of his investigation and signs it, when it is returned to the order or complaint department. The date of execution and name of man are entered on the record and the duplicate taken from the pack of outstanding orders. A reply postal card is then made out from the order, stating that complaint had been made of certain trouble and asking if our inspector had attended to it satisfactorily, these cards being sent in answer to all complaints. The reply cards do not all come back, but we are sure that if the investigation or work has not been satisfactory consumer will be sure to reply. If an unfavorable reply is received, an order is sent to inspection department calling attention to unfavorable report, and when work is again completed another reply card is sent. The original order is then sent to the filing room, where all orders of every class are filed by dates under the street number, this file being used for reference from time to time and giving a complete history of all work done by the company at any house connected to our system.

A daily report is made from the order record, showing the number of complaints received, separated by classes, and showing the number of each class for same days of previous year and the accumulative number received during the past month. This report is sent to the general manager each day and enables him to keep in touch with the troubles coming up. At the close of each month a statement is prepared showing the number of complaints handled by each inspector and the number from which "unsatisfactory" reports were received on the reply cards, also showing the per cent. of satisfactory work done. This report, after being inspected and signed by the general manager, is posted in the inspection department where all men can see it. This plan of compiling the efficiency of the men has a splendid effect in stimulating them to careful and thorough work on all orders, and means a saving of time and money to the company and better feeling on the part of the public.

BUREAU OF INFORMATION.

A new departure in the office is the establishment of a "bureau of information." This bureau is located in the most conspicuous point in the office and is in charge of a clerk thoroughly posted on all general matters of the company. His duties are to direct any and all inquirers to their desired point, such as application window, teller's window, manager's office, appliance department, etc. He has charge of the list of desirable vacant houses in the city, and upon request directs the inquirer to the real estate agent who has the property in charge. This list of houses includes only those along the company's lines or mains and only those that are equipped to use the company's service. By this plan we are able to get newcomers to the city, or those intending to move, to occupy houses where we can supply them without further investment. The list is revised each day by reports made from the soliciting and application departments of houses connected and disconnected. In connection with the bureau of information, bulletin boards have been placed at each plant, shop and department of the company. Upon these boards any announcements of changes of regulations, special inducements, information of particular importance to employees and copies of all new advertising matter being sent out are posted, in order that the employees in every branch of the business may be kept in touch with what is going on, and may be in position to talk intelligently if questioned when attending to their duties, or after hours.

METER READING.

One of the most important requirements for satisfactory relations with consumers is the necessity for accurate meter reading and billing. The coupon system of meter reading cards, originated by Mr. S. J. Glass (see Fig. 1, in which only the coupons for two months

Form 13-5.

DIVISION	FOLIO	ROUTE NO
APPLICATION NO.	**DATE SET**	**DATE OUT**
MAKE AND SIZE	**MAKER'S NO.**	**COMPANY'S NO.** Constant

NAME AND LOCATION:

MAY APRIL

FIG. 1.—COUPON SYSTEM OF METER READING CARDS.

are shown), seems to be the best and safest method in use. Under his plan a slip with 12 coupons attached is made for each meter; each coupon bears an identifying number, corresponding with the account on the consumer's ledger. After the meter has been read and bill made the coupon is detached and filed for reference. The meter reader then has only the meter number and house number to direct him when he next takes the reading. By this plan no readings can be averaged or readings put down without actually seeing the meter, and as the man has no previous reading to assist him, he must use unusual care to get the correct figures.

By keeping the same men reading each month and throughout the month and not picking up extra men each month to take statements, a considerable saving can be made, as men familiar with the routes can make much faster time and will not have to go back to get meters skipped or read wrong on the first trip. The plan of posting a list of all mistakes made by the meter readers will also increase the efficiency of this department. At the close of each month a list is posted in the department showing the number of meters read by each man and the number of errors discovered. A bonus is paid to each man who makes no mistakes during the month. One month's records show 13 men read 32,000 meters with a total of but eight errors made by all these men.

OFFICE MISTAKES.

The plan of recording and then posting a list of all errors made by the consumers' bookkeepers is followed. In this list appear any errors or omissions made by them, including errors in extensions and calculations, failure to send bill to proper address, omission of balance owed for previous period, and so forth. This posted list has the same stimulating effect as the lists of errors made by the meter readers and trouble-men.

In the general office a Dey registering time clock is used. All office employees are required to register as they come into and leave the office. From this record the office time is kept. We find it of particular value in impressing promptness upon all employees; and as clerks are on duty from seven a. m. to midnight, it is possible to know the time they arrive and leave without requiring the chief clerk or a time-keeper to note their movements. A list is posted each morning of any who have registered late in arriving or who have overstayed the hour off for lunch. At the close of each month a list is made of those who have been prompt and punctual throughout the month.

CARD RECORDS.

The use of card index records in offices is constantly growing and is satisfactory for most purposes. We are now using a house record (see Fig. 2) index in our application and order department.

STREET *No.*

Order Number	NAME	Nature of Order	Date Issued	Date Executed	Ill. Gas Meter No.	Fuel Gas Meter No.	Electric Meter No.	Index

FIG. 2.—HOUSE RECORD.

A card was made for each house connected, and as orders were taken to connect, disconnect, or change meter, arc lamp, etc., a posting to this effect was made on the house card; after the order had been executed the date of execution was entered on the card, so that we constantly have a record of our standing at each house. This has done away with all duplicate or wrong orders. Under the old plan of listing orders in a book or books we frequently sent men to re-read meters for a new tenant when we had just ordered the meter returned on instructions from the old occupant; but with the house card to refer to before sending order to shop for execution, a wrong order is detected and new one substituted to cover the latest development, or the order previously sent out is ordered recalled.

Visible-writing typewriters with card-holder attachments are used on all orders of every description. We find by their use fewer errors in copying and reading addresses and that names of consumers, being more legible than when written by hand, are correctly carried through the records and to the addressing machine.

The filing cabinet referred to before is also a feature in the card system. A guide card is placed for each street and number, and back of it are filed all completed orders for setting or removing of meters, complaints, connection of appliances, etc. If it is desired to refer to any original order, it is readily located by this plan.

For the record of stock of materials carried, a loose-leaf system is in use. One sheet is arranged for each article, showing amount on hand and received in one column, the amounts sent out in another, and a column to show the running balance of materials on hand.

This record is kept to show both the quantity and value of each article in stock, and is kept up each day from the storekeeper's reports of materials received and sent out.

ACCUMULATED REPORTS.

After the monthly report is complete, the records therein shown are transferred to loose-leaf sheets containing columns for every item on the report; these figures are carried on an accumulative basis and always show the results for the past twelve months, this being done by adding or deducting the difference between the last month and the corresponding month last year, from the previous yearly total. These accumulative figures show much more clearly any real increase or decrease, and are not misleading, as the results for any one month might be. From these accumulative sheets a year's report can be made without any trouble or delay.

OFFICE LABOR-SAVING DEVICES.

In Mr. Anthony's paper, read before the convention last year, he described several of the labor-saving methods in general use. I will therefore refer only to some not mentioned by him.

We use a Boettescher & Knecht machine in the teller's cage for receipting all bills. This machine is driven by an electric motor. The bill is placed in front of the machine by the teller, who then touches a spring; this releases the lock and sets the machine in motion, the bill is drawn under the roller, the coupon cut off and dated and dropped in a drawer below and the receipted bill forced out to the front of the window, where it may be picked up by the consumer.

We are now using an adding machine made by the Universal Adding Machine Company, of St. Louis, which has an electric driving attachment. Instead of pulling down a lever, as with the usual adding machine, a spring is touched which sets the machine in motion and performs the same office as the lever.

Self-adding sheets are a simple arrangement used in tabulating results such as number of meters or consumers gained or lost, and so forth. The sheets are ruled for units and every tenth space is so marked. When all marks are down the number of vertical spaces times the number of horizontal spaces used shows the total desired.

The slide rule frequently used in engineering work can be made to play an important part in modern office methods. Clerks can be easily instructed in its use and calculations requiring multiplication or division worked out in much less time than by the old methods.

The Thatcher calculator made by the Keuffel & Esser Co., New York, we have found the greatest labor saver yet tried. All costs and receipts are worked out on the reports on a basis of current made or sold. With several hundred separations, it will require a couple of days' time to do the division required. By the use of the calculator the results may be set down as fast as one can read the numbers on the machine. This machine is unique in construction and easily understood. Where a constant multiplier or divisor is used the results are shown more quickly than with any of the other calculating machines. This feature therefore makes it particularly valuable in use on monthly reports.

A tube system, such as is used in department stores, has been of great benefit to us. We have connection at all windows in the accounting office direct with the bookkeeping and collection rooms. If a copy of a bill is desired or explanation required, the detail can be secured in much less time than by going to consult the books and leaving the consumer waiting. We are able to do all bookkeeping work on another floor of the building, which is away from all the disturbance of the public office. We find that by this plan our bookkeepers are able to handle more accounts and with fewer interruptions.

We are installing a Hollreith electric tabulating machine. This machine is now in successful operation in a number of railway accounting offices, in some large factories, and was used by the United States Census Bureau in compiling its statistics. The equipment consists of two parts: The punch, into which properly printed cards are set, transfers the information by punching a hole in the proper space. When all information has been transferred to the punched cards they are set in the tabulating machine, which sorts them into several kinds and then compiles the information. It is our intention to use this machine to tabulate our records of all consumers, to show the possibilities of each class of business, and to use it in making up the pay-rolls. Use will also be made of it in our engineering department in keeping track of our current made, sold and lost, of the various types and efficiencies of transformers and meters.

Your reporter received his appointment at such a late date as to prevent his making inquiries among the different members as to their experience with any new office methods or labor-saving devices. I have therefore only mentioned some of the methods now employed in the Denver office. We have endeavored to kep in touch with all the newer plans suggested for accounting and for labor saving, and have adopted any that seemed to have advantages over those previously employed.

STEAM GENERATION.

An analysis of steam generation enables us to determine what proportion of the generating expense should be charged to each class of current sent out from the station. The generating apparatus for the different kinds of service is usually not of the same efficiency. To compensate for this we apply the average efficiency of the apparatus to the output in kw-hours of each class of current. This gives us at the throttle valve of the engine the equivalent of the output from each class of current. From this point the generating expenses proportional to output are common. Having this equivalent steam energy, we can divide the generating expense in the same proportion that this equivalent energy appears. This would give us expense proportional to output, which should be charged to each class of service. The expenses proportional to capacity should be divided in proportion to the capacity of each class of apparatus in the station.

Test of Westinghouse-Parsons 400 KW Steam Turbine.

In December last Messrs. Dean and Main, of Boston, made an elaborate test of a 400 kw steam turbine at the works of the Westinghouse Machine Company, East Pittsburg, Pa. As is well known, these works are provided with all facilities for the most accurate steam consumption tests of engines of the largest size. In making the present tests the condensed water was measured at intervals of ten minutes and the brake horse power was determined by means of a water dynamometer of the Froude type. The duration of the tests was two hours for the full load test with 100° superheat, and one hour for most of the other tests, though a few were made 20 to 30 minutes in length. The accompanying table gives the results of the principal test.

TEST OF 400-KW STEAM TURBINE.

Dry Saturated Steam.	Overload.	Full load.	Med'm load.	Low load.
Revolutions per minute	3,481	3,545	3,583	3,602
Throttle gauge pressure	153	154	156	156
Vacuum	26.87	26.84	26.80	26.90
Ratio of rated load	1.26	1.02	0.77	0.42
Steam per brake hp-hour	13.63	13.91	14.48	16.06
Superheat, 100° F.				
Revolutions per minute	3,457	3,546	3,580	3,588
Throttle gauge pressure	150	156	154	153
Vacuum	27.10	27.06	27.10	27.10
Ratio of rated load	1.31	1.02	0.77	0.41
Steam per brake hp-hour	12.07	12.41	12.86	14.62
Superheat, 180°.				
Revolutions per minute	3,477	3,542	......	......
Throttle gauge pressure	151	154	......	......
Vacuum	27	27.10	......	......
Ratio of rated load	1.32	1.02	......	......
Steam per brake hp-hour	11.17	11.45	......	......

Tests were also made to determine the variation of the speed of the turbine at different loads. This variation in the test with steam superheated to 100° F. was 2.5 per cent. below speed at rated load, for 31 per cent. overload, the figures for 77 per cent. load and 41 per cent. load being .9 and 1.2 per cent. below rated speed, respectively. In the test with dry steam the variations were 1.8 below normal for 20 per cent. overload; 1.60 per cent. above for 42 per cent. load, and 3.4 per cent. above for friction load.

The report contains curves showing the effect on economy from superheat, which indicate that the saving is 1 per cent. for every 10° of superheat between the limits employed in the tests.

The report calculates the thermal efficiency of the turbine tested for the several different conditions of operation. Since the thermal efficiency of a reciprocating steam engine is usually referred to indicated horse power, and as the tests of the turbine were in terms of brake horse power, in order to have a common basis for comparison it was assumed that the friction of a reciprocating engine is 6 per cent. On this basis of internal steam horse power, the thermal efficiency for dry steam is given as 17.22 per cent.: for 100° superheat 18.43 per cent., and for 180° superheat, 19.43 per cent.

Recent Electrochemical Developments.

INDUCTION FURNACE.

In the metallurgy of iron and steel electric furnace methods have been commercially successful up to the present mainly along two lines, the production of ferro-alloys and the manufacture of special high-priced steels. The high temperature easily attainable in the electric furnace is of decisive importance for the production of certain ferro-alloys, on account of the high reduction temperatures of the oxides treated. On the other hand, for the production of special steels (which have to compete with our crucible steels) no specially high temperature is required, since the process is essentially a smelting operation, and in this case the cleanliness and easy control of the electric furnace operation, the impossibility of impurities being introduced into the charge from the fuel or fuel gases (because there are none) and the ease of treating any large quantity of charge in a single operation are of signal importance. The only difficulty to be solved in this case is the prevention of impurities being introduced into the charge from the electrodes, as we generally say, although the term is improper, since no electrolytic action takes place; the "electrodes" are here nothing but terminals by which the electric current is introduced into the charge from the external source of current.

The most radical course of solving this difficulty is to use no electrodes or terminals whatever, but to introduce the electric current into the charge by inductive action in the same way as electrical energy is transported from the primary of a transformer to its secondary. In fact, the induction furnace, as operated by Kjellin, at Gysinge, in Sweden, for the production of special steels, is essentially a transformer; its primary winding, having a large number of turns, is supplied with high-tension alternating current, while the secondary has a single turn and is constituted by the charge to be melted. However, the furnace design of Kjellin seems to be capable of improvement. The efficiency of his furnace is rather low. According to *Electrochemical Industry* (December, 1903, page 578) the

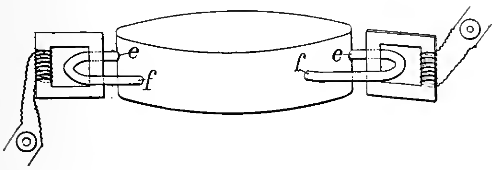

FIG. 1.—SCHNEIDER INDUCTION FURNACE.

electric power supplied to the primary is 165 kw, of which 87.5 kw are lost and only 77.5 kw are utilized in the secondary. The efficiency is, therefore, only 47 per cent.

In a patent, granted on June 7, G. P. E. Schneider, of Le Creusot, France, remarks that if the secondary (i. e., the charge to be treated) is made in form of a single ring of uniform cross-section, the current induced in it will be unnecessarily high and the reaction of this current upon the primary coil will produce an unfavorably large phase difference in the primary circuit. Schneider proposes, therefore, to increase the resistance of the secondary by making it in form of a tube of small cross-section, communicating at its both ends with a crucible of large dimensions containing the greater part of the charge. The latter part of the charge will then be at a considerably lower temperature than the charge in the tube. The one end of the tube is at a higher lever than the other end. Under the influence of the difference in density of the charge in the tube and in the crucible, an active circulation of the charge will result. The general principle of his idea will be seen from Fig. 1, which shows one large crucible in combination with two induction furnaces: one of the ends, *e* and *f*, of the tubes is at a higher level than the other. It is, of course, also feasible to have both ends at the same level, and to provide means for tilting the furnace chamber whereby the line joining the outlet and inlet of the tube may be thrown out of the horizontal plane.

The specification of Schneider's patent also contains some interesting suggestions concerning the application of the electric induction furnace, not as a substitute for, but in combination with, ordinary metallurgical furnaces. This is quite a promising idea and should in no way be confounded with the several schemes of replacing our blast furnaces by electric furnaces for making pig iron. It is easy to concentrate by means of the electric current a high heat at a certain point and at a certain stage of the operation. Thus, in his recent presidential address before the American Electrochemical Society, Dr. J. W. Richards suggested the auxiliary use of electric heating to take off "the peak of the load," so to speak, in our open hearth steel furnaces; that is, to furnish the last few hundred degrees of necessary temperature, while the combustion of gas furnishes the lower range.

Schneider's patent specification contains several suggestions of this kind. We may mention only the combination of the induction furnace with a blast furnace. Fig. 2 shows the vertical and hori-

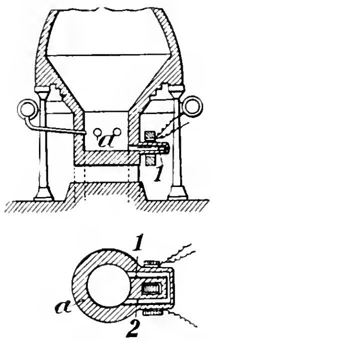

FIG. 2.—SCHNEIDER INDUCTION FURNACE.

zontal cross-section of a blast furnace, the crucible, *a*, of which is provided with the heating tubes, 1 and 2. The crucible, *a*, may thus be supplied at any stage of the operation with additional heat by electrical means. The electrical energy could be easily and cheaply provided by using part of the blast furnace gases for the operation of gas engines coupled to electric generators.

BATTERY INVENTION.

A patent granted to J. von der Poppenburg refers to the construction of a storage battery plate, in which cross pieces adapted for dividing or separating the active material protrude from the frame on both sides and are provided with holes at the part protruding from the frame; through these holes pass elastic bars, which press or bear against the protecting strips that prevent the active material from dropping off. The object is to obtain, in case of an expansion of the active material, only a bending of the elastic bars and to prevent the formation of wide cracks.

Two patents granted to G. F. Atwood refer to the composition in specific proportions of the two solutions used in the two compartments of primary batteries of the Bunsen type.

MISCELLANEOUS.

A patent, granted to H. Blackman, refers to the construction of an anode for use in electrolysis of sodium chloride. It is an iron or steel plate, the surface of which is completely covered with a dense layer of iron oxide. Several methods of producing this cover of oxide are described. This anode is stated to be incorrodible, except at the surface of the electrolyte. At this point it is, therefore, provided with a protecting band of glass of vitreous glaze.

A patent granted to G. Cornara refers to the production of explosive cartridges by producing explosive gas mixtures by electrolysis and igniting the mixture by an electric spark. As electrolyte he uses an aqueous solution of caustic soda or potash; the gas produced is, of course, a mixture of hydrogen and oxygen. Applications to blasting holes formed in rock and for projective torpedoes are described.

The Metric System in Great Britain.

The House of Lords of the British Parliament has passed a bill establishing the metric system as the legal system of Great Britain. It is confidently expected that the bill will be passed by the Commons at the next session, almost a majority of the members having committed themselves as in favor of the system.

Ohio Independent Telephone Association.

About 200 independent telephone men attended the meeting of the Ohio Independent Telephone Association, held at Columbus recently. An address of welcome was made by H. A. Lanman, president of the Columbus Citizens' Telephone Company, which was responded to by G. P. Thorpe, attorney of the Wilmington Home Telephone Company. Mr. J. B. Hoge, of Cleveland, then addressed the convention outlining a plan of organization. Two hours were profitably spent in discussing various subjects that had been placed in a "Question Box." Cyrus J. Huling, of Columbus, made a report on the post-office telephone fight, which was made in Washington last winter, showing how the independents had carried their point.

The committee on permanent organization presented a set of rules and regulations for the government of the association, after which the following-named officers were elected: President, Frank L. Beam, Columbus. Vice-presidents—W. Wilber Thompson, Lebanon; G. P. Thorpe, Wilmington; James B. Hoge, Cleveland; R. E. Hamblin, Toledo; J. C. Reber, Dayton; Dwight E. Sapp, Mt. Vernon; G. A. Mathany, Lima; W. F. Laubach, Akron; J. B. Rhodes, Zanesville; E. E. Knox, Portsmouth, secretary, and Ralph Ramer, Columbus, treasurer and assistant secretary. An executive committee consisting of five members, of which the president is ex-officio chairman, is yet to be appointed.

The plan of organization is to divide the State into nine districts, each vice-president to take charge of a district and organize the same so as to make a complete union of interests. Reports to the convention showed a very satisfactory condition throughout the State.

Mr. Harry Gates, of the Queen City Telephone Company, Cincinnati, made an interesting report stating that work had been commenced on the Cincinnati plant, and that they expected to have their plant in full operation inside of the next two years. He said that franchises would be asked for immediately in all adjoining suburbs.

Municipal Ownership in Canada.

In the return of reproductive undertakings operated by municipalities in Ontario, it is stated, in an official report, that out of 14 cities, 106 towns and 134 villages, to which forms of inquiry were sent, returns had been received by the 18th of November, 1903, from 12 cities, 90 towns and 118 villages. Of these, 11 cities, 57 towns and 21 villages had been carrying on reproductive undertakings and a number of the others reported that they were about to acquire waterworks or electric lighting plants. There are 79 municipalities in Ontario which own their water works, 35 which have their own electric lighting plants, 4 which supply electricity, 2 supply gas, 2 have municipal cemeteries, 1 possesses a dock, and 1 operates its own street railway. There was an average annual loss on the municipal street railway and electric lighting system combined at Port Arthur of $1,370.95, for the period of four years ended December 31, 1902. Profits are shown in 44 cases and losses in 48. In one case there was no profit or loss, and in 23 no reports were made. The municipal gas plant at Brockville, which was established in 1901, realized an annual profit of $4,000 on an invested capital of $85,000, but the natural gas sold by the corporation at Kingsville showed a loss of $243.38 on an invested capital of $27,000. The business of supplying electricity to consumers by municipalities has been begun too recently in most cases to admit of statistics of profit and loss. In Bracebridge there was an average annual profit of $620.28 on electric lighting and electric supply combined, which were first provided by the town in 1895; but at Hespeler, where the system was established in 1900, there was a loss of $3,084.60 on an invested capital of $15,483.48. There does not appear to have been any investigation as to the exact nature and realization of the alleged profits.

Telephony and Electric Light In New York.

A bright and amusing book on the United States, entitled: "Dollars and Democracy," has just been issued by the Appletons, from the pen of the portrait painter, Sir Philip Burne-Jones, Bart., who was over here not long ago. It is light and skittish in touch and makes no effort at serious discussion of American affairs, but makes many shrewd comments on public affairs, manners, society, etc. Sir Philip remarks that when he returned to British soil there were three things he missed above all: the domestic bath arrangements, the telephone service and the electric light. We feel we must quote him fully as to the last two:

"In New York and indeed generally throughout the United States, a telephone has become as necessary a part of the equipment of a well-appointed house as the aforesaid bath itself. The instrument is in constant use, and invitations to dinner and the opera are frequently transmitted by this expeditious means. How pleasant it is, when one feels lonely or depressed, to call up a friend and hear his cheerful voice across the city. In New York it is the exception not to have a telephone."

Sir Philip is even more emphatic about the electric light:

"The third thing I miss is the electric light—that really gives light. The bastard product of science and commercial enterprise known by the same name in London bears little resemblance to its transatlantic namesake. I think Broadway at night, with its myriad brilliant lamps, the names of its theatres and restaurants picked out in blazing points of electric fire, is a sight not readily to be forgotten, and one which impresses itself upon the imagination as much as anything in the great city of which it is the principal thoroughfare. The Waldorf-Astoria at night is also impressive at a respectful distance, but the effect on the spectator of them both is due to the brilliancy and purity of the electric light as manufactured in New York. I can do without 'rapid transit'; I can do without a 'quick lunch' (the very words give an indigestion); but I now know what baths, telephones and electric light can be under the most favorable conditions—and henceforth I shall have a new standard in mind for all three which I fear has not yet been attained in England."

The Telegraph in Presidential Election Years.

When the Western Union Telegraph Company announced $157,000 decrease from last year in its net earnings for the quarter, most people, says the New York *Evening Post*, jumped to the conclusion that this reflected the vanished pool room business. A little reflection showed that, since bills for telegraph contracts are not settled daily, the effect of the discontinuance order of May 19 would hardly be left until near the quarter's end. The company's officers, however, ascribed the decrease to the fact that whenever a Presidential election approaches "business is dull and receipts of the telegraph company grow smaller."

This sounded reasonable. It aroused, however, some interesting queries as to another equally well-known tradition—namely, that the company prospers immensely during the campaign itself, because of the increased use of the telegraph. There is an easy way to ascertain the facts. Following is the increase and decrease in Western Union's net earnings for the last three quarters of each of the six past Presidential years. Comparison is made in each case, of course, with the year before:

	JUNE QUARTER.		
1900	− $51,803	1888	+$250,538
1896	− 182,649	1884	− 5,636
1892	+ 221,440	1880	− 85,536
	SEPTEMBER QUARTER.		
1900	+ $38,189	1888	+$400,468
1896	− 255,116	1884	− 166,832
1892	+ 49,623	1880	− 334,835
	DECEMBER QUARTER.		
1900	+$133,345	1888	+$426,660
1896	− 57,962	1884	− 239,584
1892	+ 105,751	1880	− 502,613

This is a rather perplexing exhibit, and seems to prove nothing very conclusively. It should, however, be remembered that 1896 was a year of great depression; and that in 1880 the two rival telegraph systems were slashing rates in a life and death struggle.

Chicago Lighting.

The Chicago City Council has ordered two bills to be prepared. One will enable the city to regulate the price of gas and the other will authorize it to own and operate gas and electric light plants and to sell gas, electric light and power. Mayor Harrison has taken the initiative in this proposed municipal ownership of public utilities, considering it advisable to strengthen the case of the city in its contentions in the courts, with a specific grant covering these points.

CURRENT NEWS AND NOTES.

NEW YORK STATE TELEPHONY.—The annual meeting of the New York State Independent Telephone Association will be held at the Genesee Hotel, Buffalo, on June 23 and 24. A number of prominent independents will be present and an interesting programme is being prepared, while a good attendance is expected. Mr. T. S. Lane, of Buffalo, is the secretary.

SUBMARINES FOR THE EAST.—It is said that the submarine electric boat *Protector* has been shipped eastward by the Lake Submarine Torpedo Boat Company for Japan, to be succeeded by others. Meantime the United States Navy is making elaborate tests of some of the latest Holland boats, of which it is also whispered shipments to the scene of war have been made. It is all very vague and indefinite, but the inference is that "something is doing."

NEW RÖNTGEN-RAY TUBE.—Dr. J. Mount Bleyer has announced that he has discovered a special class of glass peculiarly adaptable for Röntgen rays. He found on experimenting that this glass fluoresced bluish, and on making a number of crucial tests he discovered, much to his surprise, that a tube gave out bi-ultra-violet rays in combination with Röntgen rays, much richer than he had ever observed before from any tube made from other kinds of glass.

TROLLEY AND STEAM.—The *Wall Street Journal* has the following note: "A banker who has just returned from a Western trip says: "Railroad earnings in the central West are being affected by electric railway competition. In Ohio and Indiana electric traction is developing rapidly and is cutting into steam road passenger earnings. Within the past month sleeping cars have been put on the electric lines between Indianapolis and Columbus, and between Indianapolis and northern Indiana towns. The fare on electric sleeping cars, including berth, is less than the fare on steam roads."

CONTROL OF WIRELESS.—It is stated from Washington that the joint Army and Navy Board has postponed until next fall the consideration of the question of control of wireless telegraph systems operating along the coasts of the United States. The army members of the board informed the naval members that they were not ready to make a report at this time, owing to pressure of other duties. The proposition came up on a request of the navy for the co-operation of the army for the control of wireless systems to be under the direct supervision and management of the navy, while the army officers of the joint board did not submit any reports. Gen. Greely, the Chief Signal Officer, has submitted his views to the General Staff, advising against any interference whatever with commercial line systems of wireless telegraph, maintaining that, in case of war, the government would take control of such systems, as it would of telegraph and cable lines operated in or to and from the United States. Gen. Greely also points out that the signal corps is now introducing and operating a satisfactory system of wireless telegraphy at different points, which it is proposed to use as a part of the signal corps' regular work. The indications are that the army is in no hurry to accede to the proposition of the navy. This whole subject has recently been fully discussed in these pages.

LETTERS TO THE EDITORS.

Electrical Trade With South America.

To the Editors of Electrical World and Engineer:

SIRS:—We are constantly in the market for electrical supplies of all kinds and should like to have catalogues and lowest export prices on such goods. Of course, we are in possession of the addresses of some American factories, but we should like to have others to compare prices. However, we would mention that quotations should in all cases be given f.o.b. vessel, New York. We now have before us a number of catalogues from different concerns in the United States and would probably have sent for some of these goods, but we are unable to compute freight from point of shipment inland to New York. All our European quotations are based f.o.b. Hamburg. We can thus easily figure total cost, which is impossible on, say, a shipment originating in one of your central States, like Ohio or Illinois, on account of not knowing rates from these points to New York. In the case of electrical novelties it would also be advisable to send a sample, so that one can judge if the article is worth importing and at the same time get correct import duty. We do not mean by this, however, that we expect manufacturers to send articles of value, merely as samples.

Now regarding the addresses of correspondents. Invariably letters coming from the United States with few exceptions have simply the name of addressee and Buenos Ayres, S. A. In the case of first-class mail, this is not so bad, but on printed matter such as catalogues, etc., nine cases out of ten they are not delivered. Buenos Ayres has a population of nearly a million, and the postal service is tolerably good here in the capital; but such punctuality or exactitude as in Europe, or as we suppose also in the United States of America, is not practiced here. Therefore, especially all catalogues should in all cases have full street address or post-office box "Casilla Coreo" number.

BUENOS AYRES, S. A. JENS HOLM HANSEN.

A Suggestion for Independent Telephone Companies.

To the Editors of Electrical World and Engineer:

SIRS:—The growth of independent telephony has often been pointed out in your columns, and no one who in any way tries to keep in touch with this interesting movement can fail to realize that as far as local service is concerned, the development has been very gratifying. This does not mean that the writer necessarily is a believer in competition in telephony, but as "we are confronted with a condition and not a theory" in the matter, an impartial observer likes to see the service of both Bell and independent organizations improved in every possible way.

There is no doubt that some of the independent people are making vigorous efforts to extend their long distance connections. It probably will not be long before the Middle West and the Atlantic seaboard will thus be in communication. Such a far-sighted policy is a mark of broad progress, and to one who stands outside the telephone business it is significant of commendable enterprise.

The point which I wish to make is, that many of the smaller independent companies do not as yet realize the full benefit of exchanging business with their neighbors or of offering through toll connections to distant points. The situation is, in many communities, a good deal like that which characterized the electric railway field about ten or fifteen years ago, when interurban lines were few and far between, and service between neighboring cities was of the haphazard variety, if indeed there was much of any service at all. The different independent companies use a great variety of apparatus; overhead line construction is in numerous cases little adapted to long distance conversations, and the traffic arrangements between adjacent organizations offer an attractive field for improvement.

It would seem that much progress toward more extensive business and greater profits might be made by some of the independent companies if they would settle down to a common basis of operating their systems. Certainly the various independent conventions have done much to foster an esprit de corps among competitors of the Bell organization, but in the writer's opinion it is better to adopt other methods than abuse in trying to gain a foothold in any given community. Good service at reasonable rates is the thing which counts and not an indiscriminate hurling of unpleasant epithets at one's rivals.

How can this common basis of operating be secured? There are several means of attaining it, but the writer believes the best course to be one which is comparatively undeveloped at present. We can take a leaf from the centralized control or better management of electric railway, power and lighting systems in finding the answer. It is a well-known fact that small systems of every kind usually have little extra money to pay for expert advice and oversight. As a result, the service is generally much below the standard set up by large and prosperous companies. If, then, several independent telephone companies will pool their issues and unite in securing the advice of some recognized expert in each branch of telephone work, they can secure many of the advantages of expert management at a comparatively small outlay for each individual company. Thus, in matters of engineering, it would certainly be profitable for a consulting telephone expert to advise, say, a dozen small companies at one or two hundred dollars a year apiece, and it would be an immense advantage to the different companies. In a small organization, the engineering problems which require expert knowledge of the highest order in their solution do not come up often enough to make it profitable to employ a permanent engineering staff in daily work, but when these problems do arise, the entire future of the company's business may depend upon a correct and skilled solution. Inasmuch as only a comparatively small part of such a consulting engineer's time is required to attend to the wants of each particular company, the arrangement may be highly profitable to all parties concerned. In the same way the traffic problems may be laid before an expert retained by several different independent companies, who will guarantee to increase the business of each company by at least the amount of his retaining fee, or else charge nothing for his particular service. Legal advice, also, is open to the same possibilities.

All this does not signify that a centralized financial control is essential—only a concentration of expert advice. The principle of sharing something by individual contribution which would in itself be too expensive for individual maintenance in its entirety is an old one in economics, but the writer believes it is not sufficiently realized in the independent telephone field of to-day. As an advocate of increased efficiency in every kind of electrical service the writer feels justified in calling the attention of the independent telephone world to a method of improving its service which is bound to produce results, if care is exercised in choosing the expert who will divide his services among the united companies who employ him.

Chicago, Ill. Chas. L. Roberts.

DIGEST OF CURRENT ELECTRICAL LITERATURE.

Dynamos, Motors and Transformers.

Voltage Drop in Direct-Current Generators.—Behn-Eschenburg.—An illustrated article in which he first compares the relative merits of two methods devised by him and Rothert, respectively, for determining the voltage drop in an alternating-current generator. The characteristic feature of his own method is that from the short-circuit curve of the generator different values of the internal impedance are calculated for different degrees of saturation of the magnetic system. These values of impedance multiplied with the current are then assumed to give the counter e.m.f. The error of this method is the supposition that the magnetic reluctance of the system for a certain e.m.f. of the magnetic coils excited by a direct current is not influenced by the m.m.f. of the secondary winding carrying alternating current. This supposition is correct as long as the magnetic reluctance is approximately constant, i. e., as long as the curve of the voltage of the generator, as function of the excitation, is approximately a straight line. The supposition is also approximately correct for strongly saturated generators, if the magnetic saturation is essentially produced by stray fields which cut the magnetic coils, but not the secondary coils, or on the other hand if a large amount of the magnetic field of the secondary coils does not cut the primary magnet coil. Rothert's method also uses the short-circuit curve; he therefrom calculates the equivalent of the m.m.f. of the magnet coils, corresponding to a certain counter m.m.f. of the loaded secondary coils. Here the supposition is made that the magnetic reluctance of the total system remains constant if the sum or difference of the m.m.f. of the magnet coils and of the m.m.f. of the secondary coils, as derived from the short-circuit current, remains constant. This supposition is fulfilled as long as the magnetic reluctance of the generator remains approximately constant; it is also fulfilled if the total magnetic fluxes produced by the magnet coils cut the secondary coils without stray fields, and if the total magnetic fluxes of the secondary coils cut the primary coils. Both methods are, therefore, not exact. The author gives a simple mathematical treatment of the subject and shows how by a simple correction the results obtained by both methods may be rendered correct.—*Elek. Zeit.*, May 19.

Charging Gas Retorts.—Guarini.—An illustrated description of electrically-driven machines for charging gas retorts with a uniform layer of coal of suitable size, at a speed which can be regulated, and without scattering or wasting the material.—Lond. *Elec. Rev.*, May 20.

Boilers.—A long report of competitive tests made between two different types of boilers at the plant of the Pacific Light & Power Company, at Los Angeles, Cal.—*Jour. of Elec.*, April.

Steam Turbine.—Falley.—A brief illustrated article on the De Laval steam turbine.—*Rose Technic.*, May.

Traction.

Leicester: an Automatic Reversible Booster.—An illustrated description of the municipal electric tramway system of Leicester recently described in these pages, which gives information in detail relating to the storage battery auxiliary. The battery consists of 240 cells, capable of giving 600 amp. for one hour, or 900 amp. for short periods; it can be charged normally at 270 amp., or at 450 amp. for short periods. An automatic reversible booster set is provided which consists of a shunt-wound motor, fed from the bus-bars, and a differentially-excited booster, directly coupled on one bed plate. The booster is connected in circuit with the battery and is used for raising the bus-bar pressure to the amount required for charging the battery or for raising the pressure of the battery when discharging. It is rated to give a current of 250 amp. at 130 volts on the charge, and 600 amp. at 70 volts on discharge. The machine is capable of dealing with an overload of 25 per cent. at any pressure between 20 and 70 volts, and delivers the above-mentioned currents at any pressure between zero and the maximum pressure indicated. A shunt-wound motor, working at 500 volts and running at a speed of 650 to 700 r.p.m. is employed, and the set is provided with the necessary auxiliaries, switch gear, etc. One of the main features of this system is the use of the Thury automatic pressure regulator for automatically maintaining a constant load on the generators running in parallel with the battery. The booster armatures are drum-wound with a slightly channeled core, and the coils are held in by driving horns, a double-wound armature is employed, and each winding is connected to a commutator, one at each end of the machine. The two armature coils can be connected in series or parallel as required. In the design of the reversible booster special attention has been paid to meeting the rapid changes of load and voltage without sparking. With these armatures the winding on the smooth core is placed as near as possible to the periphery and with the tangentially-arranged field coil the iron in the field magnets is reduced to a minimum. The combined efficiency of the reversible booster set is 81 per cent. After a six-hours' run at full load the temperature rise does not exceed 70° F. Fig. 1 gives a diagram of connections of the Thury auto-

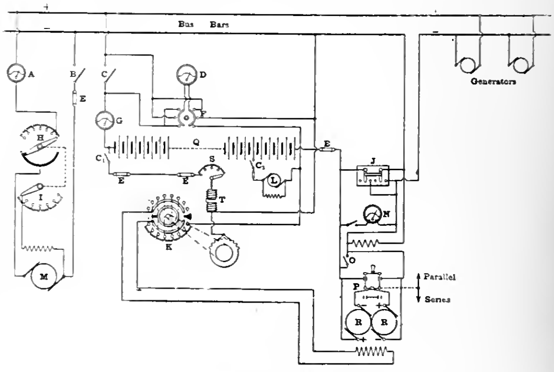

FIG. 1.—DIAGRAM OF REVERSIBLE BOOSTER.

Canton-Akron Railway.—A description of an extensive interurban railway in Northern Ohio. All dispatching is done by telephone. Every car carries a portable box telephone, which may be used at any point on the line on tapping the telephone wire by means of a long bamboo rod carried on the car. In addition to passenger traffic, the company does some express business.—*St. R'y Jour.*, May 28.

Trolley Harp.—An illustrated description of a trolley harp, the principal feature of which is the method by which the wheel is enabled to turn freely in going around curves. The loose mounting of the bearing blocks permits the trolley wheel to twist in the forks of the harp, one of the bearing blocks remaining stationary and the other sliding forward until it abuts against one of the retaining levers. The trolley wheel shaft is held against rotation as it is formed integral with one of the bearing blocks.—*St. R'y Jour.*, June 4.

California Railway.—Some notes on the San Diego & Coronado line in Southern California, which has some novel features, among them the use of a double-deck car. Owing to the distance from large manufacturing plants a number of repair shop tools have been developed. Oil is used as fuel.—*St. R'y Jour.*, June 4.

Electric Power in Metallurgical Plants.—The first part of a profusely-illustrated article on electric aerial suspended tramways for quickly transporting materials from one part of a metallurgical plant to another. The system described is that of Kolben & Co. for special use in iron and steel works.—*Elek. Bahnen.*, May, No. 10.

Electricity for Mine Hoists.—An illustrated article on electrically-operated versus steam-driven mine hoists. Some examples from various plants are described. The losses in steam pipes, operating pumps, ventilators, hoists and other mining machinery by engines of small capacity, as well as the low efficiency of these engines, make the use of electric power preferable.—*Sc. Am.*, June 4.

INSTALLATIONS, SYSTEMS AND APPLIANCES.

Rapidly-Growing Western Central Station.—BARTH.—An illustrated description of the generating plant of the Kansas City Electric Light Company, which had in 1899 a maximum load of 900 kw, while in 1903 it was 3,400 kw. The growth was so rapid that many makeshifts had to be resorted to. The company had a number of stations throughout its territory, with no less than 42 generators of various sizes and makes. The new station was finished in 1902, the equipment consisting of six double-deck water tube boilers rated at 514 hp fitted with traveling link grates, a traveling coal conveyor and ash remover being also installed: two 2,250-hp Allis-Chalmers vertical cross-compound engines drive 1,500-kw, 6,600-volt, 25-cycle alternators. The station supplies all the current for the series arc lights in the western part of the town and in the immediate vicinity. All of the 60-cycle alternating current for incandescent lamps is also furnished from here and the 6,600-volt, 25-cycle current is carried to uptown sub-stations, which are described. As the company has had so many different types of stations under its control, under similar conditions as to wages, price and quality of coal, and efficiency of management, it has determined the relative economy of the different apparatus. Data are given in the article. On May 31 the station was flooded by the rising of the Kaw River, but current was again on the lines eleven days after the flood, and the only loss which could be traced to the flood was some small potential transformers, which did not receive the proper amount of care in the drying-out process.—*Am. Elec.*, June.

ELECTRO-CHEMISTRY AND BATTERIES.

Conductivity and Fluidity.—HOSKING.—In a former investigation the author has found that the specific molecular conductivity and the fluidity of the solutions investigated by him became zero at the same temperature, viz.: 35.5° C., this result being obtained by extrapolation. Another general result obtained by him was that the fluidity-concentration isothermals and the conductivity-concentration isothermals all cut the axis of zero fluidity and conductivity respectively at the same point, representing a concentration of 10.74 normal. The author has now made an extended study of lithium chloride solutions. He finds that both the fluidity and conductivity values can be expressed by equations of the same form, and that they are proportional to the mth power of the temperature measured from a fixed point below zero degree C., which is the same for all solutions. This temperature is 48.10° C., while m varies for the different solutions. He makes some remarks on Kohlrausch's hypothesis that ions in aqueous solutions are surrounded by watery atmospheres carried along with them and the resistance the ions have to overcome is mainly friction between this atmosphere and the solvent water.—*Phil. Mag.*, May.

ELECTRO-CHEMISTRY AND BATTERIES.

Gold Refining.—WOHLWILL.—An illustrated article on his electrolytic process of gold refining, which is now in use in the Philadelphia Mint. Its main features are the addition of hydrochloric acid to the electrolyte of gold chloride and the use of an elevated temperature. If the anode is gold containing platinum, both gold and platinum pass into the solution, but only the gold is deposited upon the cathode. The platinum can be precipitated from the solution afterward in a very simple way. The author points out that all natural silver and gold contain platinum, and that the refiner should endeavor to recover the platinum, which can be easily done by electrolysis. He also speaks of iridium and palladium.—*Electrochem. Ind.*, June.

Extracting Copper from Ores.—JONES.—An illustrated paper on the methods of leaching and precipitating copper, in use at Rio Tinto in Spain. Huge heaps of the mineral are allowed to oxidize under the influence of moisture and air and subsequently the copper sulphate is washed out as soon as it is formed by running water through the heap. The liquor is run into the precipitation tanks over pig iron to precipitate the copper in the form of so-called cement copper. While thus the process does not contain the application of an electric current, some of the reactions are electrochemical in nature, due to the occurrence of galvanic couples in the tanks. The method of working is described in detail.—*Electrochem. Ind.*, June.

Chemical Applications of N-Rays.—COLSON.—In a continuation of his researches in which he observed that N-rays are given off during certain chemical reactions and that they can be utilized as a physical criterion for such actions he has now found that the chemical reactions which give rise to N-rays are invariably accompanied by some physical action such as contraction or cooling. Some very vivid chemical reactions, such as a precipitation of salts are not accompanied by any evolution of N-rays, so that there is evidently no proportionality between the chemical action and the evolution of N-rays. It is just this lack of proportionality which makes the N-rays valuable to the chemist, since he is thus enabled to discover actions which may be masked by the more evident chemical reactions.—*Comptes Rendus*, May 21; Lond. *Elec.*, May 20.

UNITS, MEASUREMENTS AND INSTRUMENTS.

Multipolar Electrostatic and Electrodynamic Instruments.—MORRIS.—In the discussion of Duddell's paper abstracted in the Digest last week, he said that the working forces in an electrostatic instrument could be increased by limiting the angular range without increasing the amount of inertia of the moving system. For instance, this can be effected in the quadrant electrometer with a wide needle by subdividing the quadrants in a similar manner. The needle would then have the same total moment of inertia as before. If the fixed quadrants are similarly divided into sectors, then the working forces are increased. The force available for use depends upon the angular rate of change of capacity of the needle; and although by the change described, the actual capacity (and therefore the capacity current) have not been increased, yet a very small angular movement is required for the needle to pass from the position of maximum capacity to that of least capacity. The limit to this process of subdivision in the case of zero or small deflection instruments is decided by the practical working clearance, the clearance being determined by the tilting of the needle due to unbalanced electrostatic forces. Small charges on the parts due to contact potential differences render low-voltage electrostatic working very troublesome. Both these troubles are, however, simultaneously avoided by using a separate needle attached to and in the same plane as the other, but insulated from it, and connected electrically with the other set of sectors. On this principle an instrument was constructed of a cylindrical type. In order to measure small alternating-current voltages on an ordinary potentiometer, the needle was brought back to zero by a small direct current, flowing in a little dynamometer coil attached to the mirror. These principles have been adopted in some of Addenbrooke's sensitive electrostatic instruments. Such an instrument might be called a multipolar electrostatic instrument, and he has used the same idea in the construction of a multipolar electrodynamic instrument. Air is, after all, but a poor conductor for magnetic lines, and there is no reason why it is necessary to provide enough coils to send a reasonable flux into spaces such as the center of a dynamometer or wattmeter of any given type where the flux is not wanted. This only causes inductive error. He supposes that the inductive errors depend very nearly upon the volume of the space, which is filled with the alternating flux. The sides of the moving coil of an ordinary dynamometer, or even of a modern high-class wattmeter, occupy but a small part of the space so magnetized. If, however, both the fixed and moving coils are wound multipolar, then, though the angular range is restricted, the sensitiveness might be increased and the inductive error clearly very much reduced.—Lond. *Elec.*, May 20.

Measuring the Effective Resistance and Inductance and the Energy Loss in Alternating-Current Apparatus.—Dolezalek.—An illustrated description of a method based on the principle of the Wheatstone bridge. The apparatus, the effective resistance and inductance of which are to be determined, is placed in series with a non-inductive resistance box in one arm of the bridge. The ordinary galvanometer of the bridge is replaced by a telephone, in order to send first alternating currents through the system. Balance is first obtained by sliding one terminal contact of the branch which contains the telephone along a measuring wire and by adjusting the resistance box. The alternating current is then disconnected and a galvanometer substituted for the telephone and direct current is sent through the system. The current in the galvanometer branch is brought to zero by adjusting the resistance box. This last adjustment gives directly the difference of the effective resistance of the apparatus for alternating current and the ordinary ohmic resistance. This difference is due to the hysteresis and eddy-current losses, etc. If it is multiplied with the square of the current one gets the loss due to hysteresis, eddy currents, etc., in watts per second.—*Elek. Rund.*, May 15.

Telegraphy, Telephony and Signals.

Alarm Bells Tuned to Alternating Current of Given Strength or Given Frequency.—Baumann.—In the continuation of his article, the first part of which was abstracted in the Digest last week, the author first described the use of alarm bells tuned to a certain strength of alternating current. The principle is shown in Fig. 2.

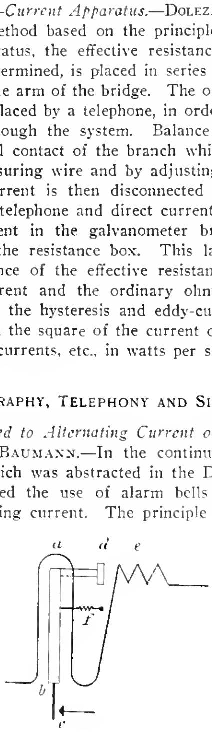

FIG. 2.—ALARM BELLS.

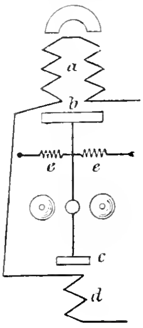
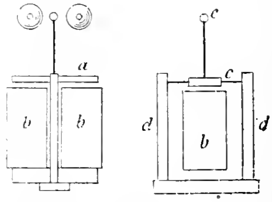
A relay is provided consisting of two coils, *a* and *c*. One of them, *a*, surrounds a permanent magnet, *b*, which can revolve in a horizontal plane. The one terminal of the permanent magnet has a torque which closes the contact, *c*, when it is displaced under the action of the current; at the other end of the permanent magnet a perpendicular piece of soft iron, *d*, is provided which is opposite to the pole to the electromagnet, *e*. If an alternating current passes through both coils, the permanent magnet is subjected to two actions. The coil, *a*, tries to remove the permanent magnet out of the plane of the coil while the action from *e* and *d* tries to hold the magnet. In the same sense spring *f* is acting. The first force is proportional to the current, the second is proportional to the square of the current, while the third is constant. It can be easily shown mathematically that the magnet is deviated only if the current is between two certain limits. A tuned bell, based on the same principle, is shown in Fig. 3; *a* and *d* are electromagnets. The springs, *e*, try to hold the clapper of the bell in its central position. If the current is small, the clapper remains at rest. If it is increased *a* will act on *b* and the bell will ring. If the current is further increased the action of *d* upon the soft iron piece, *c*, will be greater than the action of *a* upon *b* and the clapper will be at rest. Fig. 4 shows an alarm bell tuned to a certain frequency of an alternating current. The armature, *a*, of a polarized electromagnet, *b*, is perforated in its center, a steel wire, *c*, passing through, which is fixed at the two posts, *d*. If the period of the alternating current is equal to the natural period of the





FIGS. 3 AND 4.—ALARM BELLS.

oscillations of the system, *a*, *c*, *e*, it will begin to vibrate and the bell will ring. The natural period of this system can be easily adjusted by regulating the distance of the armature from the magnet poles and the torsion of the wire, *c*.—*Zeit. f. Elek.* (Vienna), May 15.

Transmission of Pictures.—Ennsbruner.—An illustrated article on the electric transmission of photographs, pictures and writings. This has been tried repeatedly with the aid of the well-known property of selenium having a greater electric resistance in the dark than in light. The author describes the system of Korn. The features of this system are essentially the methods of keeping two rolls in synchronous rotation at the transmitting and receiving stations and to correct at certain time intervals any difference in synchronism. In the receiver he uses a vacuum tube, the radiation of which is changed by the currents received from the transmitter. At the transmitter the rays passing through a small part of the picture at any moment fall upon a selenium cell and cause its resistance to change.—*Elek. Neu. Anz.*, May 15.

Railway Signalling.—A description of the system of signalling adopted on the Boston and Worcester electric railway, by which the dispatcher can summon to the telephone any car crew and give orders. The telephone wires extend the entire length of the line, with instruments at all turnouts, and pads on which orders received by the car crew are written down in pencil and copies preserved in the box. Adjoining each telephone is a signal box containing semaphore signal, pendulum and magnet, each pendulum being of different length. The dispatcher in the main office, by means of a 75-mm. cog wheel, can send electrical vibrations through all of the electromagnets, and by timing the vibrations the pendulum whose period is synchronous with a period of the electromagnetic impulses will commence to vibrate, tipping the lock holding the semaphore in a vertical position. When the semaphore falls it closes a lamp switch giving the luminosity signal needed at night. After the motorman has reported to the main office and received his orders, he resets the signal to "clear."—*St. R'y Jour.*, June 4.

REFERENCES.

Telephone Engineering.—Dommerque.—Another of his series of articles on telephone engineering. He treats of three kinds of protective devices used on telephone circuits; that is, lightning arresters, strong current protectors or fuses, and sneak current arresters or heat coils. Lightning arresters are to protect against atmospheric electricity and high-tension currents; strong current protectors or fuses, against currents of electric light, power and all circuits of moderate potential; heat coils, against sneak currents caused by leakage or poor insulation. The author describes the various devices on the market.—*Am. Elec.*, May.

Wireless Telegraphy.—Collins.—A long and well-illustrated description of the modifications and improvements which wireless telegraph apparatus have undergone since 1896. He describes the type of transmitter of 1896, various types of telegraph keys, induction coils, interrupters and spark-gaps, the type of receiver of 1896, various relays, decoherers, electric wave detectors, Marconi's magnetic wave detector, and various inductors.—*Eng'ing. Mag.*, June.

Cable Steamer.—A fully illustrated description of the cable steamer

Pacific, which has been built for the Great Northern Telegraph Company as an addition to its cable repairing fleet. Three cable tanks have been provided which will hold about 450 miles of deep-sea cable—say 1,000 tons.—Lond. *Elec.,* May 20.

MISCELLANEOUS.

Nerve Impulses and N-Rays.—CHARPENTIER.—An account of the investigation in which he has proven the existence of a wave propagation of nerve impulses and determines their wave length by means of N-rays. If, instead of using a single wire for the conduction of N-rays, two wires are used, their combined effect upon the screen is sometimes weaker and at other times stronger than the effect of a single wire. This suggested to him the existence of interference, and since the intensity of N-rays emitted by a nerve, is proportional to the activity of the nerve it was reasonable to suppose that the nerve impulses have a definite frequency and wave length. He therefore examined a nerve at two points by means of two wires of equal length and found that there was no effect upon the screen when the points were 16 mm. apart. This he considers to be half the wave length of the nerve impulses and their frequency is about 800 per second.—*Comptes Rendus,* May 2; Lond. *Elec.,* May 20.

Fire Hazards in Electric Plants.—KNOWLTON.—An article in which the author gives numerous detailed rules on precautions against the occurrence of fire in electric plants and on means of extinguishing the flame when once a blaze has started. He thinks that the greater proportion of fire hazards are preventable, and that careless operation is at the bottom of most of the trouble. Inside an electric plant water is of no value in putting out an electric fire, and for this reason automatic sprinklers are undesirable; extinguishers of the dry powder, chemical or compressed gas types, are far more effective for all around service. Fires caused by electric arcs are best beaten out by asbestos or woolen blankets, overcoats, towels, etc., or else quenched by the liberal use of sand. The entire wiring system ought to conform to the practice of the National Board of Fire Underwriters. To prevent confusion in case of a fire, due to the failure of the lighting current, either oil or candle lanterns should always be provided. An automatic fire alarm which will give warning of any unusual temperature rise beyond safe limits is a necessity in all plants which are divided into several rooms, such as telephone exchanges. A few hundred dollars go a long way toward completely protecting all but the largest plants from all fires except those which are unpreventable. —*Eng. Mag.,* June.

New Books.

THE THEORY OF THE LEAD ACCUMULATOR. By Dr. F. Dolezalek. Translated by Dr. Carl L. von Ende. New York: John Wiley & Sons. 252 pages, 30 illustrations. Price, $2.50.

This is a valuable and interesting little book, written along the lines of the newer electrochemistry and presenting a good summary of modern theory on the subject of the lead storage battery. It may be said in general to limit itself to the theoretical side of the topic, but there are many references to practical tests and results. The book is divided into some sixteen chapters, although some of these deal with tables and measurements. The three opening chapters discuss the subject from the standpoints of the chemical, osmotic and thermodynamical theories of the origin of current, not elaborately, but succinctly; still with sufficient clearness and fullness in proportion to other parts of the treatise. It is notable that German and English authorities are cited frequently; American are conspicuous by their absence. But who could blame the author for that? Other chapters treat of variation of electromotive force with acid concentration, and variation of electrode potential; temperature coefficient; influence of external pressure; behavior during charge and discharge; reversibility; changes in the open cell; internal resistance; capacity; degree of efficiency and working efficiency; changes in the cell during formation. A final chapter deals with methods of measurement, and there is also a table of density and percentage strength of mixtures of sulphuric acid and water. An excellent index is furnished.

AMERICAN STREET RAILWAY INVESTMENTS (The Red Book for 1904). McGraw Publishing Company, New York. 362 pages. Price, $5.

This valuable annual record of street railway investments has again made its welcome appearance, and maintains its growth and improvement in make-up and quality of contents. This year's volume is larger than ever before and contains reports of a considerable number of companies which hitherto have declined to present financial statements. In addition to a large increase of information of this character, the publishers have added a number of other useful features, among them the location of power stations and repair shops, parks and pleasure resorts, and much more complete descriptions of the funded debts of the different properties.

The volume also contains a large number of maps of the principal street railway systems in the country, many of them in two or more colors; also some novel and striking maps showing the interurban railways in New Jersey, Ohio, Indiana and Illinois.

The analysis of the earnings of the different properties as reported this year indicates that they have kept up in spite of the decrease in many of the steam railroads and manufacturing properties, and as a whole the industry can be said to be in a prosperous condition. In a comparison for 1903 and 1902 of the gross receipts of 310 companies, the average increase is 8.5 per cent. These figures vary, of course, in different groups or categories, but all the data go to show that the street railway industry to-day, as ever, demands new capital and material, and yields a fair return thereon. It is worth the while of any political or social economist to sit down for an hour or two with this handsome volume and master its many revelations and suggestions, as well as direct data, as to the course of electric transportation in America.

Cooley Rotary Engine.

An engine proof against the effects that usually follow neglect to properly lubricate, sudden turning on or off of power, reversal when under full speed, sudden flooding of water, unintelligent tightening up of wearing parts and lack of attention to ports liable to work loose, and which at the same time will still do its duty and maintain a fair degree of efficiency under the above conditions is claimed to be that made by the Cooley General Development Company, of Boston, and which we illustrate herewith. The simplicity of the engine is brought out in Fig. 1, showing the engine with the cylinder head removed and exposing the working parts. Fig. 2 shows all that there is of the working parts withdrawn.

When the engine is in motion the four short roller valves, *A*, roll upon the interior of the cylinder, thereby effecting a nearly frictionless condition of what would cause the greatest frictional loss with a block or slide valve when under centrifugal influence, the same influence in this case merely rendering more certain the rolling of the valves. The diameter of these valves is so proportioned to their length that binding at their extremities through canting is stated to be impossible, their end surfaces being sufficiently large to maintain alignment. They are practically the pistons of

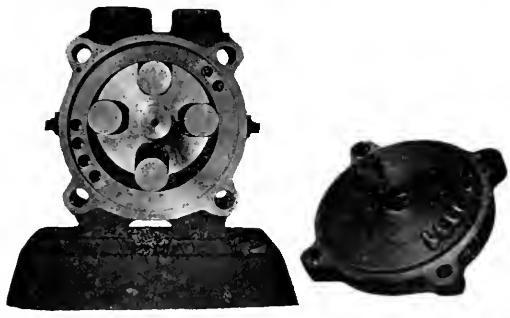


FIG. 1.—ENGINE WITH CYLINDER HEAD REMOVED.

the engine, their distances from the axis of the shaft determining when under steam pressure the leverage and effective piston area of the engine.

In Fig. 1 the upper and lower valves, being the greatest and least effective in causing rotation, may be used as an example. Steam pressing on both of these valves simultaneously from the right will cause a rotation of the engine in the direction of the movement of the hands of a watch because of the greater leverage of the lower valve. The upper valve acts to maintain a joint at the top, and as rotation continues, oppositely located valves consecutively perform these functions. The slotted hub is of cast iron while the valves are of steel insuring fairly good wearing conditions. The cylinder is double, having an annular steam space within the outer wall and completely surrounding the inner wall except at the top and bottom, where partitions are provided to separate the exhaust from the entering steam. A steam jacket is thereby provided by which the inner wall of the cylinder is maintained at a temperature almost exactly equal to the temperature of the slotted hub and valves, thereby practically removing the serious drawback of differential expansion.

The slotted hub and the valves are slightly shorter than the cylinder, the latter being about 2/1000 of an inch shorter and the former 1/1000 of an inch shorter, in a 10-hp engine, which is sufficient to allow their free movement between the cylinder heads. The slight leakage of steam consequent to this condition is less than the amount of loss that would be occasioned by friction if mechanical joints were maintained between the heads and the working parts; the leakage is preferable because it allows cheaper construction, better

FIG. 2.—PARTS OF ENGINE.

economy and less likelihood of cutting and other troubles when oiling is neglected. The entrance and exit of steam are effected through the small holes in the upper right and lower left of counterbore of the cylinder end. They open at both ends of the cylinder, and both cylinder heads are grooved to allow the entrance of steam at both ends of the valves simultaneously and between the slotted hub and the valves as well as into the cylinder.

This method of porting insures a non-broken surface of the interior of the cylinder both while machining it and for the valves to travel over when in actual operation. The exhaust is of large area and free, the mere passing of the valves by the port grooves in the heads effecting a cut-off of steam between consecutive valves and resulting in a useful expansion of the steam which in the engine illustrated corresponds to about one-half cut-off.

Endurance tests have shown, it is claimed, that the engine will stand up and maintain good working conditions under shocks and strains that would instantly wreck a reciprocating engine or other motor of less rugged and enduring qualities. Below are the data of a test made at the shops of the New York Central & Hudson River

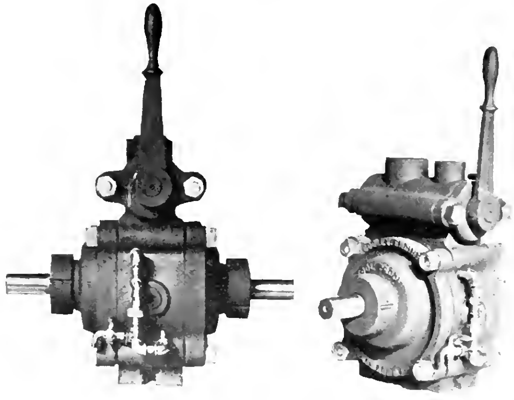

FIG. 3.—TWO VIEWS OF COOLEY ENGINE.

Railroad Company at West Albany: Duration of run, 7½ hours; boiler pressure gauge average, 98.13; average r.p.m., 1,249; total condensed water, 1,358 pounds; developed horse-power, 9.79; length of brake arm, 5¼ ft.; mechanical efficiency, 91 per cent.

The trial consisted of nine separate runs of one-half hour each, readings being taken every five minutes during each run. The exhaust steam was condensed in a surface condenser, the condensing water caught and weighed after each run. A separator was used to dry the steam, with a throttling calorimeter to detect the moisture present. Readings of the thermometer on this were taken every minute throughout the runs. The developed horse-power was measured by a Prony brake. The first run was made with no load to determine friction and thereafter a load increasing by one pound each run was put on.

Willard Storage Battery for Automobiles.

The accompanying illustrations, Figs. 1 and 2, show in detail the improvements lately made in the Willard storage battery. The Willard Co. has fully realized that one of the greatest troubles in vehicle batteries is due, not so much to the character of the plates, as to their tendency to short circuits, and that while the short circuiting from face to face of the plates has been corrected by the use of wood

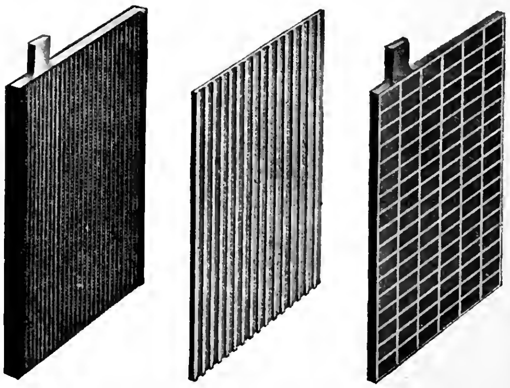

FIG. 1.—STORAGE BATTERY PLATES.

separators, there is still left the probability of the plates short circuiting around the edges and bottoms. This trouble has been corrected in a very simple and effective way by enclosing the positives in an envelope of hard rubber, finely perforated along the faces, but imperforate along the edges and bottoms. With this envelope or

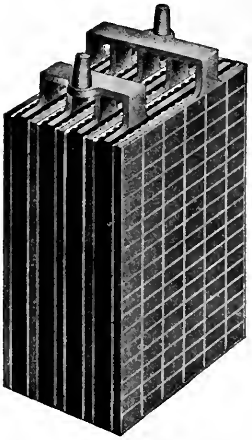

FIG. 2.—ASSEMBLED PLATES.

sheath, there is used a grooved, imperforate sheet of specially treated wood, thus, it is said, entirely doing away with any possibility of short circuit, either across the faces or around the edges of the plate, yet at the same time allowing free electrolytic action and circulation between adjacent plates.

The Willard Co. states that the sheath used with its positive plate is not a new device, as it was successfully used several years ago in connection with its standard batteries, but that its cost at that time precluded any idea of its general use. The company has recently put in new apparatus for producing these sheaths and so reduced the cost as to make their general use practicable.

The company still uses its familiar form of Planté positive, consisting of a sheet of pure rolled lead having fine, vertical grooves, but has changed to a cage type of pasted grid for its negative plates, in this way adopting the particular combination of Planté and Faure plates, which experience has shown to give the highest voltage and longest life.

In the regular type of battery, the straps connecting the plates together are provided with pillar type terminals over which fit covers of molded and reinforced hard rubber. This system is found to do away entirely with the trouble experienced sometimes by the acid slopping and siphoning over the sides of the jars. Ordinarily the cover is sealed in with a compound which makes the jar practically acid-tight, but in some special types the jars are deeper and the covers set in lower down, without sealing. The nine-plate cell shown in the accompanying engraving weighs thirty-two pounds and has a capacity of thirty-six amperes for four hours.

Electrical Exhibits at the St. Louis Exposition.

The office of ELECTRICAL WORLD AND ENGINEER is elegantly and comfortably furnished for the reception of visitors. Complete files of its technical journals and a library of electrical books published by the McGraw Publishing Company are at the service of visiting engineers. A register is kept in which it is intended to have a complete record of all those interested in electrical industries who go to the Exposition. Comfortable and cosy seats and lounges are provided for any who wish to read and facilities are at hand for correspondence. The booth is below the office gallery of the Electrical Department, and its appearance may be noted from the accompanying illustration. It is a great centre and rendezvous for electrical visitors at the Exposition.

FIG. 1.—BOOTH OF "ELECTRICAL WORLD AND ENGINEER."

The Burdette-Rowntree Manufacturing Company has an exhibit of automatic electric dumbwaiters at the northwest entrance of the Electricity Building. The exhibit consists of two complete installations of push control electric dumbwaiters, one running at a speed of 150 feet per minute and the other at nearly 600 feet per minute. Both cars run from the floor to the highest part of the roof of the building. The high speed car is enclosed in glass and contains incandescent lamps that light up automatically when the car is in motion. The most interesting part of this exhibit is the automatic feature that makes the installation what the manufacturers call "fool-proof." The car is operated by means of push buttons, placed both on the enclosure work and on the adjacent desk. In actual practice, they can be located on every floor, so that the car can be operated from any floor, or only from one floor; and by this means one man only has control of its movements. Pressure for an instant on any button causes the car to start, and it automatically stops at the floor corresponding to the button depressed. It is not necessary to keep the finger on the button while the car is in motion. If a button is pressed while any door is open it will not cause the car to start, or while the car is in motion it will have no effect. One cannot open a door, if doorlocks are used, unless the car is at that floor. If doorlocks are not used, and the door is opened while the car is in motion, it immediately stops the car.

The car always automatically slows down before stopping and so comes to rest smoothly and easily. So perfectly is this done that in actual practice a glass brimming full of water can be placed in the car and a round trip made without spilling a drop. The high speed car is operated from the adjacent desk, and has also a signal lamp on the desk which lights up when the car is at rest, and goes out while it is in motion, or when any door is opened. The operator knows therefore the instant the car starts, the instant it has reached the floor to which it was sent, the instant the door is opened by the attendant on that floor, and when the door is again closed and the car is ready for use.

FIG. 2.—BURDETTE-ROWNTREE EXHIBIT.

Just across the aisle is a complete operating exhibit of the Dayton Electrical Manufacturing Company. A Fairbanks-Morse 20 hp gas engine is direct coupled to a 200-light dynamo, which supplies the current for operating the exhibit and lighting the large sign. This engine is ignited by either jump spark, touch spark or the new Apple electric flame at the option of the operator. On the switchboard a new design ignition meter shows the number of charges taken in by the engine and the number of charges ignited by each of the three systems mentioned above, thus showing the comparative merit of each. On a long table there are one dozen flywheels of various sizes operating 24 ignition dynamos fitted with Apple gov-

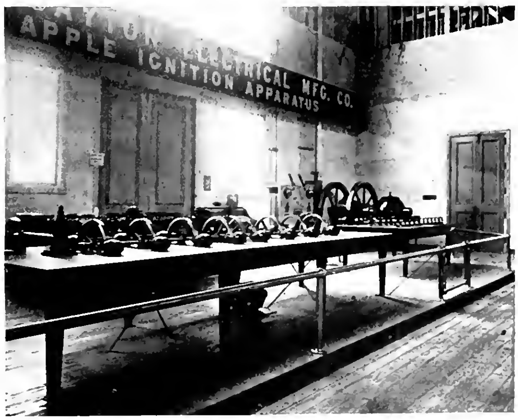

FIG. 3.—DAYTON ELECTRICAL MFG. CO. EXHIBIT.

ernors that maintain the speed of the dynamo constant no matter how fast the gas or gasoline engine may run. In addition are shown storage batteries, jump spark coils, contact coils, plugs, timers and magnetos made by this company. It is a very interesting exhibit.

One of the operating exhibits to which all are attracted is the Hall model electro-plating establishment in the west doorway of the building. The complete operation of gold and silver plating is shown from cleaning the metal surface, depositing the coating, cleaning and polishing. Perhaps the most interesting feature of this exhibit are the electro-plated leaves, fruit and flowers and other non-metallic substances. By a special process there is deposited upon the surface a copper coating, and then the gold or silver plating can be quickly done. The cleaning and polishing is done within glass cases so that the dust and dirt attending such work is entirely absent.

In the Robbins & Myers space a very creditable showing is made of a line of their "Standard" motors and dynamos. These machines are shown in sizes from 1-30 to 15 hp, and these cover the capacities built by the company. One machine is disassembled to show the methods of construction, insulation and the interchangeability of parts. The unique feature of the entire exhibit is an immense revolving fan motor rack. A rack with six arms rests on a ball-bearing upon a center post. From extremities of each arm is suspended a ceiling fan, and above each arm is a desk fan with the plane of the fan nearly parallel with the arm. With the twelve fans going, the desk fans cause the entire rack to revolve, which keeps the air of that entire section in circulation. Another interesting exhibit item is a magnetic separator used for extracting particles of metal from cotton before it reaches the gin.

The generator and motor exhibit of the Triumph Electric Company covers a wide range of application. Power for operating this exhibit is derived from a Warren synchronous motor driving a 35-kw, 220-volt Triumph generator. There is also a Fairbanks-Morse vertical gas engine direct connected to a 7½-kw, 220-volt generator, this set being a good example of the minimum floor space required for a small power station. A motor generator set takes current from the above source and delivers 10 kw at 500 volts. A number of tools are shown in operations illustrating the method of connected Triumph motors to same. A Fay & Egan band saw is driven by a motor and intended for one speed only. The motor-driven Bickford radial drill is regulated by a Cutler-Hammer drum starter and controller. A Lodge & Shipley lathe is similarly equipped and in operation. All

FIG. 4.—EXHIBIT OF ROBBINS & MYERS CO.

FIG. 5.—HALL'S ELECTROPLATING EXHIBIT.

FIG. 6.—TRIUMPH ELECTRIC CO.'S EXHIBIT, AS SEEN ACROSS THE AISLE.

these tool motors are designed for 220 volts. The inoperative machinery consists of a 100-kw multipolar engine type generator and a series of power motors ranging in size from ½ to 25 horse power. A large armature core is partially wound to illustrate the method and details of construction, also other detail parts of the various machines are shown.

More and more attention is given to better hygienic and sanitary

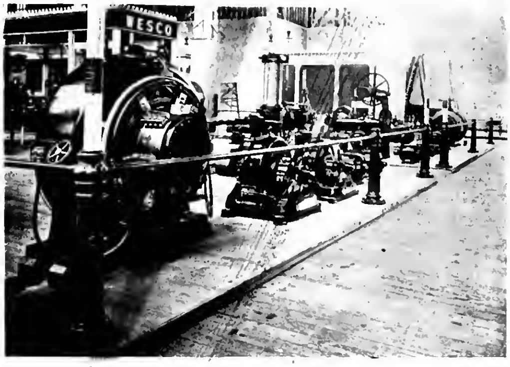

FIG. 7.—TRIUMPH ELECTRIC COMPANY'S EXHIBIT.

conditions wherever large numbers of people are brought in contact. It is claimed that one of the most fertile sources of disease transmission is the telephone transmitter, because it collects the bacteria from the breath of those speaking into the mouthpiece. The Telephone Hygenic Company's exhibit indicates how this can be obviated by stretching an antiseptic paper before the mouthpiece. The paper surface can be changed at any time by the speaker giving the roll a turn. This does not interfere with the transmission of sound, but rather magnifies the vibrations.

The Delany system of rapid telegraphy is demonstrated by a com-

FIG. 8.—HYGIENIC TELEPHONE EXHIBIT.

plete set of operating apparatus. The speed of transmission is as high as 1,000 words a minute and this is accomplished by the following means: A strip of paper passes through a perforator operated by a typewriter keyboard, and the depression of the key instead of printing the letter punches perforations on the tape corresponding to Morse characters. The perforated tape is then passed through the transmitter, and by means of contact through the perforations impulses of equal duration and alternating polarity are sent over the line. At the opposite end of the line, messages are recorded by an automatic receiver on a chemical tape. As the Morse dot and dash record is made, the tape is wound on reels and distributed to typewriters for transcription. Different modifications of parts of this apparatus are also shown in operation.

The exhibit of the Fort Wayne Electric Works is characterized by the life and light displayed. There are sixty arc lamps in and around

FIG. 9.—DELANY RAPID TELEGRAPH EXHIBIT.

the space, which make a most brilliant illumination. A handsome ten-panel switchboard is provided for distribution and regulation. From the building sub-station, two supplies of current are received, one a three-wire, 220-volt, direct-current, and the other 500-volt, direct-current. A series of motor generators convert this current for

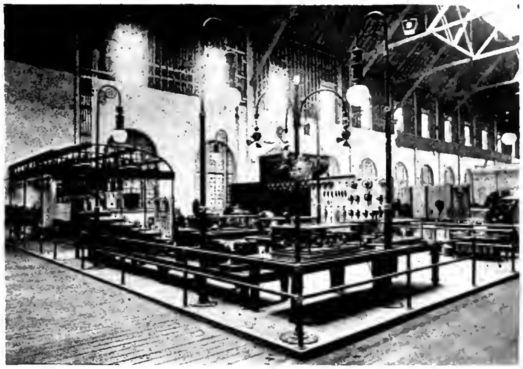

FIG. 10.—EXHIBIT OF FORT WAYNE ELECTRIC WORKS.

the different applications. The first is a 55-hp, 220-volt motor driving a 37½-kw, 1,100-volt alternator, which furnishes current to the series and multiple alternating current arc lamps. The next set consists of a 30-hp, 220-volt motor driving a Wood constant current,

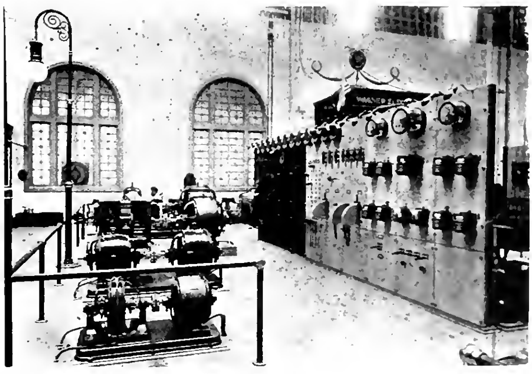

FIG. 11.—ANOTHER VIEW OF FORT WAYNE EXHIBIT.

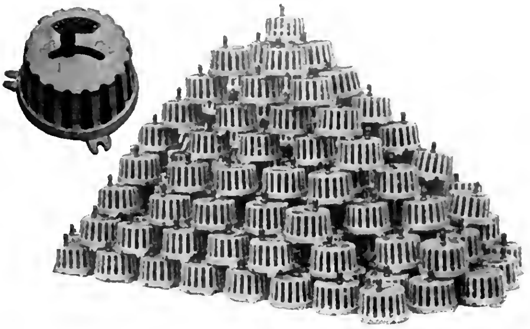
series arc, 6½-ampere dynamo of 22 light capacity. A 15-hp, 500-volt motor is direct connected to a two-phase 110-volt, 60-cycle generator which supplies current to the 20,000-volt transformer for operating the De Forest wireless telegraph stations already illustrated, one of which occupies a small space in this exhibit. Another supply of alternating current is from a 140-cycle alternator driven at 2,800 r.p.m. by a 4-hp, 500-volt motor. A line of transformers from 1 to 50-kw is displayed, as well as windings and sections showing the thorough methods of insulation. The different types of wattmeters made by this company are displayed under operating conditions on the switchboard panels and in cases are mounted all the separate parts used in the construction of these instruments. The Fort Wayne series alternating arc lighting system, as described in Electrical World and Engineer of June 4, is complete and in operation.

The most popular part of the exhibit is at the corner of the two aisles, where a standard carries a number of Fort Wayne oscillating fan motors which distribute a refreshing breeze to all who stop and watch their gyrations. Perhaps the most interesting item in the space is the arc-light machine constructed by Mr. James J. Wood, in May, 1879. It will furnish power for arc light, and it was so well constructed that after a quarter century of use it is still serviceable.

Ceiling Fan Controller.

As there has been a very considerable demand both at home and abroad for a ceiling fan controller of sufficiently fine appearance to permit of its being mounted in finely furnished hotels, restaurants, clubrooms, private parlors, etc., the Ward Leonard Electric Company, of Bronxville, N. Y., has placed upon the market a small, highly finished rheostat, as shown in the accompanying cut. The company has sent some twelve hundred of these regulators abroad to one house,



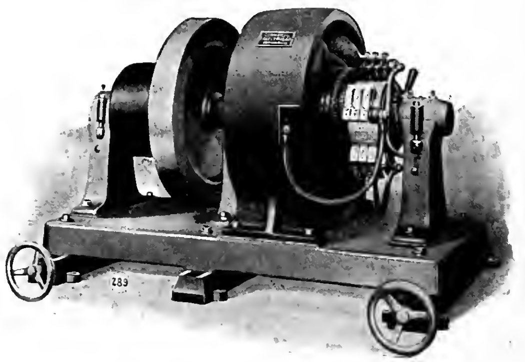
A PILE OF CEILING FAN CONTROLLERS.

Messrs. Geipel & Lange, of England. An interesting pile of them is shown in the illustration.

The resistance of this regulator consists of the well-known entirely enclosed, hermetically sealed resistance units of the company's make. These rheostats are finished in bronze, copper, aluminum or black japan finish, and make a very ornamental as well as useful instrument. The corner view shows a single rheostat of this type.

Generators for Gas Engine Plants.

In the early gas engine electric lighting work it was the habit to place all the blame for irregular running and for flickering light upon the prime motor, but the rapid improvements in this respect, of recent years, have been largely due to the design of special generators. We illustrate herewith a type, or line, of direct-current generators brought out for this work by the Commercial Electric Company, of Indianapolis, Ind. On account of the irregular impulses of the engines, it is necessary to provide a fly-wheel which will overcome the fluctuations of the dynamo speed and produce a steady light, which is impossible where the irregularities of the engine speed are reproduced in the armature of the dynamo. This requirement has sometimes been met by placing a heavy fly-wheel upon an extension of the armature shaft, without providing any additional support for this wheel. As standard dynamo bearings are generally not sufficiently heavy to sustain the extra weight of the fly-wheel, this method has generally given but slight satisfaction. In order to satisfactorily overcome these speed fluctuations without imposing unusual strains upon the dynamo parts, the Commercial company has designed special machines having an extra heavy shaft, which is extended to receive a heavy fly-wheel and which is supported by three bearings, two of which are placed close upon either side of the fly-wheel, where they will support its weight and receive the extra strain caused by the jerking of the



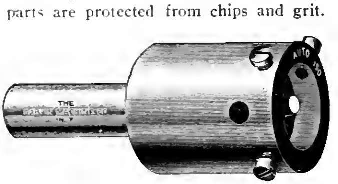
GENERATOR FOR GAS ENGINE.

dynamo belt without injurious effect upon the dynamo. These three pedestals, with the machine frame, are mounted upon a heavy iron base, which is carried upon sliding rails with hand wheels and thrust screws, by means of which the belt tension can be adjusted. By this construction the overloading of the dynamo bearings or the expense of an extra countershaft for carrying the fly-wheel is avoided, and a substantial mechanical machine, capable of producing a steady light, is secured. These machines include all the usual sizes and speeds from ½ to 30 kw.

Automatic Die Holder.

The illustration shows a new automatic hollow shank die holder for screw machines. This die holder is specially designed by the Garvin Machine Company, of Spring and Varick Streets, New York City, for high speed and overcomes many of the defects which develop in these tools, when used under such conditions. It is clutched positively, going forward, but on reverse, when the die is in rapid rotation, and must be stopped, it is held by friction grip, so that it is noiseless in action and reverses without shock and clatter, which conduces greatly to increased durability and efficiency. The friction grip consists of three rollers each resting on a small incline and embraced by a steel shell, all these parts being hardened and of substantial size.

The hollow shank permits long work to pass clear through; but the working parts are protected from chips and grit. To prevent



AUTOMATIC DIE HOLDER.

hammering, when reversing, is more difficult with a hollow shank holder than with the solid shank construction; but in using this new style of holder there is no danger of engaging the reversing clutch too soon, and hammering is done away with.

The die reverses itself instantly and automatically, on throwing the shipper, and begins to run back of itself, and requires no cooperation in starting to move the turret slide backward at the right instant and can, therefore, be operated with less skill and experience on the part of the operator. The die holder is made in three sizes.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—A sharp rally early in the week imparted a little more firmness to the stock market, but there was a lack of speculative interest. United States Steel securities were firm despite unfavorable reports as to the iron trade and the postponement of action on the preferred dividend until the end of July. Little interest was shown in any of the industrials apart from the Steel securities, and the traction group was also neglected. At the close of the week the general market was broader and more active at advances. Brooklyn Rapid Transit, on a fair amount of trading, advanced from 46¾ to 48⅝, closing at 48⅝, this being an advance of 1⅝ points. Metropolitan Street Railway became active and strong, 16,760 shares having been sold at prices ranging from 109⅝ to 114, the closing quotation being 113⅞—a net gain of 3⅞ points. The telegraph and electric stocks, with the exception of Westinghouse, showed increased strength and advances. Allis-Chalmers closed at 8, being 1 point better than the closing figure of the previous week; General Electric rose from 155, the lowest, to 159½, the highest quotation of the week, and closed at 155, thus gaining 3 points net. Westinghouse lost ⅛ of a point, closing at 156. American Telephone & Telegraph fluctuated between 125½ and 128, the latter being the closing price, and an advance of 2¾ points as compared with the last previous quotation. Western Union closed 1⅝ better off, the last quotation being 87½. The curb market was stronger in tone and prices were higher, following the lead of the main market. The feature was the strength of Interborough Rapid Transit, which advanced nearly 3 points in connection with the declaration of the first dividend. Among the specialties a sharp advance in Electric Boat was ascribed to activity in submarine boat building for war purposes. Mackay Companies common made a sharp rise, no particular reason therefore being apparent, and Electric Vehicle seemed to be under manipulation. Following are the Stock Exchange closing quotations of June 14:

ALLIS-CHALMERS ANNUAL REPORT.—The Allis-Chalmers Company issues its annual report for the year ended April 30, 1904. The income account compares as follows:

	1904.	1903.	1902.
Net profits	$952,624	$1,653,576	$1,442,259
Preferred Dividends	853,125	1,137,500	1,137,500
Surplus	$99,499	$516,076	$304,759
Previous surplus	820,835	304,759	....
Total surplus	$920,334	$820,835	....

Net profits are given after deducting operating expenses, reserve, depreciation, maintenance and repairs. To the surplus of $920,334 was added the sum of $201,951, which was the excess of par value over book cost of $100,000 preferred stock and $180,000 common stock acquired in settlement of current business contracts, etc. This makes a total of $1,122,286, from which special appropriations amounting to $497,450 have been deducted, leaving a net profit and loss surplus April 30, 1904, of $624,835. The general balance sheet as of April 30, 1904, compares as follows:

Assets:	1904.	1903.	1902.
Real estate, bldgs., plts., good will, etc.	$30,246,084	$29,199,493	$27,352,082
Bills and accounts received	3,437,520	2,475,579	2,778,721
Merchandise, materials, etc.	2,914,878	5,131,800	3,333,665
Cash	1,060,113	1,628,009	4,514,167
Bullock Electric Mfg. Company	463,000	....	....
Total	$38,121,596	$38,434,881	$37,978,635
Liabilities:			
Preferred stock	$16,150,000	$16,250,000	$16,250,000
Common stock	19,820,000	20,000,000	20,000,000
Accounts payable	1,014,396	1,079,671	1,139,500
Mortgage due March, 1905	34,000	....	....
Dividends payable May 1	....	284,375	284,375
Depreciation reserves	478,365	....	....
Surplus	624,835	820,835	304,760
Total	$38,121,596	$38,434,881	$37,978,635

President B. H. Warren says: "The fiscal year will hereafter terminate on the last day of June in each year. In the settlement of several business contracts entered into prior to March 1st, the company became the owner of $100,000 par value of its preferred stock and $180,000 par value of its common stock, which shares have been cancelled, thus reducing the outstanding capital stock to $16,150,000 of preferred stock entitled to cumulative dividends, at the rate of 7 per cent. per annum, from February 1, 1904, and to $19,820,000 of common stock." During the past year the following expenditures have been made in the increase, or for greater economy in the operation, of the productive property of the company:

Additions to plants	$642,232
New plant	77,300
Terminal railroad	49,060
Capital expenditures during the year	$768,592
The cost of manufacture during the past year has included charges for:	
Maintenance and repairs	$752,535
Depreciation	244,478
An operating expense of	$997,013

The report also calls attention to the arrangements with other concerns, and the acquisition of plants, etc., in Canada. It adds: "All the property of the company is owned in fee except the Bullock Electrical Works at Norwood, near Cincinnati, Ohio, the latter being held under a long lease. The entire property is free from mortgage or other lien, with the single exception of that for $34,000 assumed in the purchase of the Norwood Foundry, and which, by its terms, cannot be retired until its maturity, March 22, 1905. No mortgage can be placed upon the property without the assent of 75 per cent. of the amount of preferred stock outstanding."

A UNIVERSITY'S INVESTMENTS.—It were well, says *Leslie's Weekly*, if every college, as a public institution, made a full statement of its financial affairs each year. Harvard College does make such a statement. It is interesting to know some of the forms of the investment of the funds of our oldest university. Railroad stocks and railroad bonds represent a favorite investment. A hundred thousand dollars in the Chicago & Alton 4 per cent. collateral notes; a hundred thousand dollars in the Chicago Northwestern Railroad general mortgage 3½ per cent. of 1987; two hundred thousand dollars of the Louisville & Jeffersonville Bridge Company first mortgage 4s of 1945; a hundred thousand of New York Central & Hudson River Railroad 3½s of 1988, and a hundred thousand dollars of Schenectady Railway first mortgage 4½s of 1941, are entries found in a single column. A score of the great steam railways of the country are represented in the list of securities. Many street railroads, too, as those of New York, Minneapolis and Massachusetts electric companies, are found in the list. The notes also of great manufacturing companies, such as the Manchester Cotton Mills and the Merrimac Manufacturing Company, are a favorite form of investment. Manufacturing and telephone stocks and real estate trust stocks are not absent. The total is about $3,000,000.

DIVIDENDS.—The United Railways Investment Company of San Francisco has declared a semi-annual dividend of 1¾ per cent. on the preferred stock, being an increase of ¼ per cent. payable July 1st. The Interborough Rapid Transit Company of New York has declared a dividend of 2 per cent. United Gas Improvement Company has declared a dividend of 2 per cent. for the quarter. The Seattle Electric Company has declared a semi-annual dividend of 3 per cent. on the preferred, payable October 7th. The directors of Commercial Cable have declared the regular quarterly dividend of 2 per cent., payable July 1st. In accordance with the provisions of the lease of the West End Street Railway Company to the Boston Elevated Railway Company, a semi-annual dividend rental of $2 per share will be paid on West End Street Railway preferred stock July 1st. The Strowger Automatic Telephone Company has declared the regular semi-annual dividend of 50 cents per share, payable July 1st. The directors of the Railway Equipment Company have declared the regular monthly dividend of 1½ per cent. and an extra dividend of 2 per cent., payable June 15th.

WESTERN UNION REPORT.—The Western Union Telegraph Company issued last week its annual statement for the year ending June 30th, together with a statement of the business for the quarter ending on the same date. The statements are partly estimated. The annual statement shows a net surplus of $1,908,914, as against $2,268,722 for last year and $1,431,718 for 1902. The company's total surplus is $14,928,638. The statement for the quarter shows a net surplus of $340,433, as against $504,383 for 1903, $420,697 for the same quarter in 1902, and $306,391 for the quarter in 1901. The detailed figures follow:

	1904. (estimated)	1903. (actual)	1902. (actual)	1901. (actual)
Net revenue	$1,850,000	$2,007,698	$1,892,476	$1,762,436
Bond interest	292,550	286,300	254,770	239,040
Balance	$1,557,450	$1.721,398	$1,637,706	$1,523,396
Dividends	1,217,017	1,217,015	1,217,009	1,217,005
Surplus	$340,433	$504,383	$420,697	$306,391
Previous surplus	14,588,205	12,513,341	10,330,306	9,012,894
Total surplus	$14.928,638	$13,019,724	$10,751,003	$9,319,285
Twelve months:				
Net revenue	$7,934,682	$8,214,472	$7,292,329	$6,685,249
Bond interest	1,157,700	1,077,700	992,580	956,160
Balance	$6,776,982	$7,136,772	$6,299,749	$5,729,089
Dividends	4.868,068	4,868,050	4,868,031	4,868,008
Surplus	$1,908,914	$2,268,722	$1,431,718	$861,081
Previous surplus	13,019,724	10,751,000	9,319,285	8,458,205
Total surplus	$14.928,638	$13,019,725	$10,751,003	$9,319,286

The figures are generally considered an excellent showing in view of trade conditions and the lopping off of poolroom business.

NEW YORK INTERBOROUGH.—The Interborough Rapid Transit Company's directors met last week and declared a dividend of 2 per cent. payable on July 1st. This is the first dividend the company has declared. It has an authorized issue of $35,000,000 stock, all or nearly all of which is outstanding. As the subway is not completed, the dividend must be paid out of the surplus of the Manhattan Elevated. The balance sheet of the Interborough Company of June 30, 1903, showed a surplus of $547,000. The Interborough operates the elevated lines under a lease which provides that the yearly rental shall be 6 per cent. on the stock up to and including January 1, 1906, and 1 per cent. additional if earned. After January 1, 1906, the rental is 7 per cent. The Manhattan's surplus for the six months ended December 31st last, after interest and rentals had been paid, amounted to $2,621,278, as compared with $1,765,760 for the corresponding six months of the previous year.

Commercial Intelligence.

THE WEEK IN TRADE.—The iron trade was reported very dull, and production is being curtailed, but stocks increased during May. The other metals were dull and somewhat weaker, the price of copper being reduced ¼c, which, however, did not increase the number of purchases. The closing prices were 12¾ @ 13c for Lake; 12⅝ @ 12⅞c for electrolytic and 12⅜ @ 12½c for casting. The London market is lower for both spot and futures. The exports so far this month aggregate 2,994 tons. *Bradstreet's* reports 171 business failures during the week ending June 9th, against 194 the week previous and 181 the corresponding week last year. The Lake strike is still exerting a detrimental influence in many lines along the northern border. Railway earnings show the effect of the smaller movement of business in May, the aggregate of which shows a decrease of 3.5 per cent. from a year ago. April net earnings indicate a decrease of 6 per cent. as compared with the same month last year, the anthracite coal roads being conspicuous exceptions. Trade and industry are quiet as a whole, and the money market still reflects speculative depression and a curtailment of demand for money in trade circles. There is an expansion of export trade in iron and steel, leather and lumber as a result of lower prices, but there is no improvement in the foreign demand for cereals. Rains, swollen streams and cool weather in various sections have had an unfavorable effect on crop development and on retail trade in seasonable goods. Prices of nearly all classes of staple products are on the downward turn as a result of the slack demand, but it is believed in many quarters that these lower prices are in themselves a good feature, and will induce buying that higher prices had choked off, people preferring to wait.

RAILROAD TIE PROBLEM.—The railroads and trolley lines will in a few years, according to the *Wall Street Journal,* be seriously confronted with the tie problem. This is known in an indefinite way, but the day has generally been thought to be remotely in the future. The eastern railroads for some time have been able to draw only a small part of their tie supply from their own territory. West Virginia for a long time was a great resource, but the tie-producing area has moved south. The great bulk of the ties now comes from the Carolinas and Georgia, whence they are brought north by coastwise sailing vessels. The growing scarcity is reflected in the figures below, which are the average price per tie paid each year by a large eastern road: 1898, 45 cents; 1899, 49 cents; 1900, 59 cents; 1901, 56 cents; 1902, 55 cents; 1903, 60 cents; 1904, 62 cents. The advanced methods in forestry which are gradually coming into vogue are arresting the reckless forest destruction in some quarters. But the results so far are feeble and not general. The solution of the problem by using a substitute for the wooden tie is often discussed. Metal ties have so far proved a failure in America because of the great weight of the rolling stock to be sustained. Under any conditions the steel tie will always be wanting in the resiliency which is so great a desideratum to both rolling stock and track. Should it be that the electric motor will in time supersede the freight locomotive with its ponderous reciprocating parts, some part of the objection to the steel tie may be removed. It is asserted that at no distant date, the demand for steel ties alone will be a big boom for the United States Steel Corporation. There have been suggestions of ties of fibrous artificial material, of toughened glass and of asphalt. The last named proposes the use of a block of wood under each rail base. Such a tie would have weight bearing surface, structural rigidity and resiliency and would seem to be promising. Some roads have already anticipated the trend of things and have established departments of forestry, and gone into the growing of their own ties. This plan commits the railroad to a large expenditure, but it is a wise one. However, it is believed very much could be done by a forestry bureau on each railroad whose territory offers any possibilities of trees growing, such bureau to cooperate with the farmers along the line stimulating forest culture by the many agencies of education and cooperation which the railroad has at its command. The prospect of tie shortage which is coming before the railroads is due to wanton and reckless waste rather than to inadequacy of resources. With better husbanding of resources great things can be done.

CROCKER-WHEELER ORDERS.—The Crocker-Wheeler Company, through its New York City offices, of which F. B. De Gress is manager, reports recent receipts of numerous orders for generators, motors, etc., to be shipped to New York, New Jersey and Connecticut points. The Stromberg-Carlson Telephone Manufacturing Company, of Rochester, N. Y., has ordered four standard motors ranging in capacity from 15 hp to 25 hp. This is a repeat order. The New Haven (Conn.) Clock Company is to be shipped a 100-kw generator and two 50-hp motors. The J. B. Williams Co., of Glastonbury, Conn., has requisitioned for a 150-kw engine type generator. The Derby (Conn.) Gas Company has ordered two 10-hp and two 5-hp motors. The State Board of Education, Trenton, N. J., has placed an order for a 50-kw engine type generator and a 10-hp motor. The Capewell Horse Nail Company, of Hartford, Conn., is to be shipped additional Crocker-Wheeler equipment consisting of a 40-kw generator and a 25-hp motor; while six motors of various sizes have been ordered for installation in the bakery of Hicks & Schmidt, 587 Greenwich street, New York City. The New Jersey Zinc Company has called for two 25-hp standard motors for its Franklin, N. J., plant, and has also ordered three motors of the same capacity for installation in its Hazard, Pa., plant. The John A. Roebling's Sons Co., of Trenton, N. J., is to be shipped a 90-hp motor. Two 13-hp motors will be forwarded to the De La Mar Copper Works, at Carteret, N. J., while the Pittsburg Reduction Company has ordered 22 small motors to be utilized for driving fans at its Massena, N. Y., plant. Mr. De Gress states that the May orders secured in his territory show an increase of fully 50 per cent. over those taken in April, and represent the largest monthly sales so far this year.

A HUGE COPPER CONSOLIDATION.—The *New York World* says: "Announcement will soon be made of a combination of mining interests of America with John D. Rockefeller at its head. The capital of the merged companies, it is said, will be $2,500,000,000, and the purpose is to control the mineral output of the United States, with the possible exception of the Calument & Hecla copper mine of Michigan. Senator Clark's United Verde and Montana properties and those of F. A. Heinze in Montana are said to be included, as also are the principal mining companies of Colorado, Utah and California."

General News.

THE TELEPHONE.

GILLETT, ARK.—The People's Union Telephone Company has been incorporated with a capital stock of $25,000. William J. Stillwell is president.

JONESBORO, ARK.—The Automatic Home Telephone Company has been incorporated with a capital stock of $25,000. R. L. Collins is president.

SANTA ROSA, CAL.—The Westside Telephone of Healdsburg has been incorporated by J. McClish, M. V. Frost and others.

LOS ANGELES, CAL.—Articles of incorporation have been filed in the county clerk's office by the San Fernand Home Telephone Company, of which Charles F. Guthridge, Charles L. Zahm, Arthur Wright, D. F. Boyce and C. P. Platt, all of Los Angeles, are the first directors. The company is capitalized at $50,000, of which $10,000 has been subscribed.

FISHER, ILL.—The Granger Mutual Telephone Company has reduced its capital from $15,000 to $10,000.

NUNDA, ILL.—The Union Light & Telephone Company has increased its capital stock from $15,000 to $25,000.

INDIANAPOLIS, IND.—The Central Union Telephone Company has issued a new order reducing toll rates in Indiana, Ohio and Illinois. New toll lines have been built and the company is now able to handle more business and give lower rates.

EVANSVILLE, IND.—The members of the common council have decided to postpone action on the telephone question. It is generally believed that the Citizens Telephone Company is desirous of giving way to the Home Telephone Company.

MUNCIE, IND.—The Madison & Delaware County Telephone Company is preparing to make extensive improvements in its exchange and lines in this locality. Manager Bromley announces that he will be in the market for a large amount of material for the contemplated work.

CRAWFORDSVILLE, IND.—The Central Union Telephone Company is making an effort to put in a new telephone system in this city. The business men oppose it and insist that there is not room for two systems here. The Central Union maintains a toll station here.

KELLERTON, IA.—The Kellerton Telephone Company will build a line to Mt. Ayr.

WEBSTER CITY, IA.—The Martin Telephone Company has ordered two additional sections for its switchboard.

CEDAR FALLS, IA.—The Cedar Falls Mutual Telephone Company has been incorporated with a capital stock of $25,000, by N. H. Norris and others.

SPEARVILLE, KAN.—The Spearville Telephone Company has been incorporated with a capital stock of $2000.

BANGOR, ME.—The petition of the Automatic Telephone Company to enter Bangor with its lines was voted down at a special meeting of the Board of Aldermen.

CHIHUAHUA, MEX.—Governor Luis Terrazas, of the State of Chihuahua, has granted a concession for the construction and operation of a telephone line from Las Cuevas to Roncesvalles and from Morris to Socorro and other points in the State.

CITY OF MEXICO, MEX.—The Mexican Government and the city council of the City of Mexico have extended for a further period of six months the concession held by Jose Sitzenstaller for the construction of a telephone system in the City of Mexico. Under the terms of the extension the work of construction must be commenced within six months from May 4 of the present year. It is stated that Mr. Sitzenstaller is making an effort to organize a strong company to finance and carry out the proposed enterprise. It is his intention to install a complete system which will be a strong competitor of the system of the Mexican Telephone Company now in operation here.

PLYMOUTH, MICH.—A new telephone company has been formed here by J. J. Sherer, J. C. Brayton and others.

HANCOCK, MICH.—The Michigan Telephone Company will expend $50,000 in improvements to its system in this section.

ANN ARBOR, MICH.—It looks as if there was a movement on foot to consolidate the independent telephone companies of Michigan, and unite the system with those already developed in other states. The Washtenaw Home Telephone Company has already spent $25,000 or $30,000 in Ann Arbor and vicinity and is about ready to begin business.

BAY CITY, MICH.—The Michigan State Telephone Company will build trunk lines on 1000 miles of the Pere Marquette Railroad's right of way, having closed a deal with the railroad company for that privilege. By the end of the year the company will have about 70,000 subscribers, an increase of over 15,000. Rights have also been secured for trunk lines on the South Shore Road's right of way in the upper peninsula.

ST. PAUL, MINN.—The Shakopee Telephone Company has increased its capital from $3000 to $10,000.

DASSELL, MINN.—The Dassell-Collinwood Telephone Exchange Company has been incorporated with a capital stock of $25,000. The directors are S. N. Gayner, S. Oyster and others.

WATERTOWN, MINN.—The Watertown Telephone Company has been incorporated with a capital stock of $25,000. F. A. Barth is president.

ST. PETER, MINN.—At the annual meeting of the Nicollet County Telephone Company, officers were elected as follows: M. P. Quist, president; Charles Samuelson, vice-president; C. C. Nelson, secretary and manager, and P. A. Retrum, treasurer. The company was organized in 1898. The prime movers were farmers, and to-day they own the bulk of the stock, of which $19,650 is paid up. The lines cover over 150 miles of territory, distributed over Nicollet and Sibley Counties. The system has 322 telephones in operation, of which 182 are in the homes of farmers. The company also owns and operates exchanges at Gaylord, Gibbon, Lafayette and Norseland. Many improvements and extensions are in contemplation. The value of the system is placed at over $25,000.

NATCHEZ, MISS.—A long-distance telephone line will be constructed between Natchez, Miss., and Jonesville, La., by the Cumberland Telephone & Telegraph Company.

ST. LOUIS, MO.—A mortgage securing $5,000,000 in bonds of the Kinloch Long Distance Telephone Company of Missouri has been filed for record at Clayton, the county seat of St. Louis County, and copies will be placed on record in thirty-four other counties where the company owns property. The American Trust and Savings Bank, of Chicago, and Geo. W. Galbreath, of St. Louis, are named co-trustees. The bonds are 5 per cent. twenty-five-year gold and are given to pay off the indebtedness of the company and for improvements.

FORESTVILLE, N. Y.—The Conewango Valley Home Telephone Company has been incorporated with a capital stock of $11,000. The directors are A. H. Libbey, B. C. Wilson and others.

SENECA FALLS, N. Y.—A local telephone company has been organized in Fayette and the following-named gentlemen have been elected officers: President, Dr. McWayne; secretary, Fred Emens; treasurer, Charles O'Connor.

CATSKILL, N. Y.—A telephone war is on. The Hudson River Company in 1884 purchased the wires and poles of the Catskill Telephone Exchange, and for years has enjoyed a monopoly of business. Two years ago the West Shore Telephone Company secured a franchise to erect poles and string wires in the village of Catskill. The Hudson River Company has obstructed the West Shore in several ways, but the work has gone on. Last week the Hudson River Company erected a large pole on Grand View Avenue, but neglected to put on crossarms. During the night the West Shore Company strung wires which obstruct the setting of the crossarms. The manager of the Hudson River Company served notice on the West Shore that it would cut the wires. The latter called on the Sheriff of Greene County to protect the lines. It is said that the Hudson River Company never had a franchise to erect its poles. At last reports the conditions were still strained.

PHILLIPSBURG, OHIO.—The Acme Telephone Company, with a capital stock of $15,000, has been incorporated.

ROCKFORD, OHIO.—The Rockford Toll Line Telephone Company has increased its capital from $10,000 to $20,000.

FINDLAY, OHIO.—The Mt. Cory Farmers' Mutual Telephone Company has been organized with W. A. Williamson as president.

ROCKFORD, OHIO.—The Rockford Toll Line Telephone Company has increased its capital stock from $8000 to $20,000 and will make improvements.

BAINBRIDGE, OHIO.—The Bainbridge Telephone Company has been incorporated with a capital stock of $10,000. The directors are O. E. Post, C. S. Leinhart and others.

CLEVELAND, OHIO.—The Bell Telephone Company is stringing two new long distance lines between Cleveland and Columbus, two between Cleveland and New Castle, Pa., and two between Cleveland and Buffalo. Extensive improvements are being made on the Cleveland long distance switchboard.

YORK, PA.—The York Telephone Company has declared its usual semi-annual dividend of 2 per cent. payable July 1.

DOYLESTOWN, PA.—Application has been made for a charter for an independent telephone line to be operated in the upper end of the county under the name of the Franklin Telegraph & Telephone Company. Those interested are H. S. Funk, H. F. Funk, W. F. Witte, T. M. Moyer, N. S. Rice, J. J. Ott, C. B. Weaver and W. O. Ealer.

MANILA, P. I.—A telephone franchise has been applied for by the Sociedad de los Telefonos de Manila. The company will be under American management.

CHARLESTON, S. C.—The Island Telephone Company's entire outfit was sold at auction at Charleston recently for $8200, by Geo. E. Gibbon, said to be representing stockholders of the company. The system, with its numerous connections, may be operated again shortly. Foreclosure of deed of trust was the cause of the sale.

NASHVILLE, TENN.—The Gass Bridge Telephone Company, of Greene County, Tenn., has been chartered with $300 capital. W. S. Babb is interested.

CHATTANOOGA, TENN.—It is announced that the Southern Bell Telephone Company will build a long distance line from Chattanooga to Gadsden, Ala., at a cost of $50,000.

DENISON, TEX.—The Grayson County Telephone Company will spend $50,000 in improving its lines.

BROWNWOOD, TEX.—The Central Texas Telephone Company has applied to the city council of Brownwood for a franchise.

HONEY GROVE, TEX.—A. L. Hill, formerly manager of the telephone company at Smithville, Tex., will install a telephone system at Honey Grove.

SCHULENBURG, TEX.—The Schulenburg Telephone Company has been organized here with a capital stock of $5000. William E. Pertitz is one of the incorporators.

DEXTER, TEX.—The Dexter & Gainesville Telephone Company will install a telephone system in this section. The company was recently organized with principal office at Dexter. J. F. Morris, of Gainesville, is one of the incorporators.

WESTBY, WIS.—The Westby Telephone Company has increased its capital to $10,000.

LENA, WIS.—The Farmers & Merchants' Telephone Company has been incorporated with a capital stock of $4000.

ELECTRIC LIGHT AND POWER.

PINE BLUFF, ARK.—The Citizens' Light & Transit Company, of Pine Bluff, contemplates the installation of another alternator of 250 or 300-kw capacity.

BRINKLEY, ARK. The Farrell Light, Heat & Water Company of this place contemplates the building of a new plant. Mr. J. J. Farrell is the purchasing agent.

FAYETTEVILLE, ARK.—F. W. Fratt, Oklahoma City, Okla. Ter., states that it is proposed to install a new unit of from 120 to 150-kw, a two-phase alternator and an engine. J. W. McLendon, Fayetteville, superintendent, can give further information.

SPRINGVILLE, CAL.—C. L. Witten, of San Jose, is attorney for the Globe Light & Power Company, which intends to construct a power plant.

SAN FRANCISCO, CAL.—The San Francisco Gas & Electric Company, which made a bid of $400,000 for lighting the streets and public buildings for the year ending June 30, 1905, has signified its willingness to accept the figure of $320,000 allowed by the city budget. As the rival gas companies were absorbed last year, this company had no competitor in bidding for the street lighting. The bid for each electric arc lamp per night was 35 5-7 cents; number of lamps not to exceed 1111. The city is to be lighted every night in the year instead of according to the former moonlight schedule. The bid for lighting at the City Hall, Hall of Justice, etc., was 5 cents per kilowatt-hour, or $1 per thousand feet for gas. It was specified that not more than 4885 gas lamps be used. Last year, under competition, the rates were scaled down to fit an appropriation of $300,000, out of which the San Francisco Gas & Electric Company received $296,000.

SAN FRANCISCO, CAL.—The Shasta Power Company, H. L. Shannon, president, will put in the flumes and ditches and erect its 25-mile transmission line from a point on Bear Creek to Redding this fall. The first 1500-kw, three-phase Bullock generator, ordered through the Wagner-Bullock Electric Company, is expected to arrive next April, enabling the plant to be operated next summer. The power water will be diverted from Hat Creek, near Mt. Lassen, and conducted to Bear Creek, where there is a drop of 1500 in 6000 feet of pipe line. This company was recently incorporated by H. L. Shannon, T. I. O'Brien and F. Kingsbury, all of San Francisco, John W. Potts and Charles Jacobs, of Redding. The capital stock is $1,000,000 and money is available to install a plant costing $100,000. This project was erroneously reported last week as being that of the Mt. Lassen Water Power Company. The latter company proposes to install an electric transmission plant on Battle Creek, 35 miles from Redding. The company has been incorporated with a capital stock of $500,000, by C. H. Hilbert and A. Barnard, of Redding; L. M. Robbins, A. G. Sheath, M. A. Kenney and A. E. Bennett, of San Francisco.

BRISTOL, CONN.—The Wallace Barnes Company, Bristol, Conn., is building a new power house 40x60 feet, to be equipped with a 150-hp Cooper-Corliss engine which will operate a 150-kw General Electric generator. Two 100-hp Dillon boilers will furnish steam power.

WASHINGTON, D. C.—Bids will be received June 28 at the Bureau of Supplies and Accounts, Navy Department, Washington, for furnishing at the navy yards, Mare Island, Cal., and Puget Sound, Wash., a quantity of flexible conduit, rubber-covered conductor, electrical supplies, etc. Address H. T. B. Harris, Paymaster General.

BRAIDENTOWN, FLA.—The Manatee Light & Traction Company will install a series alternating arc system in this place.

CARROLLTON, GA.—It was voted June 4 to issue $45,000 bonds for water works, a sewerage system and an electric light plant.

ATHENS, GA.—The City of Athens is contemplating the enlargement of the municipal electric light plant. The present plant does not supply power enough for recent and contemplated extensions.

BARNESVILLE, GA.—G. E. Strickland and J. W. Strickland, of Pike, and associates, are applying for a charter for the Flint River Power Company. The property to be developed by the company is the Flat Shoals on Flint River, from which 5000 hp may be obtained.

ATLANTA, GA.—The development of the immense water power at Bull Sluice Shoals, near Atlanta, has developed to the point where the water has been turned into the new electric power dam. It was thought that nearly a week would be required to fill the dam.

ALBANY, GA. The town of Albany on June 9 voted on the question of a contract with the Albany Power & Manufacturing Company for supplying 300 electric horse-power annually for 17 years at $8000 each year. The company has also bought a water power near Albany which will probably be developed.

BOISE CITY, IDA.—The Highland Power Company's dam, located 20 miles up the river from Boise, was swept away by a recent flood. The power house was also badly damaged.

ROCKFORD, ILL.—It is stated that the Central Heat & Power Company will install a new electric plant this summer.

QUINCY, ILL.—The Independent Light & Power Company will increase the capacity of its plant by adding another unit consisting of a 1200-hp engine and a generator.

ELKHART, IND.—The Elkhart City Electric Company has incorporated with a capital stock of $15,000. C. G. Conn heads the board of directors.

DECATUR, IND.—The Decatur city lighting plant is to be enlarged by the addition of another Corliss engine of about 300 horse-power.

IOWA CITY, IA.—It is stated that the J. F. Hill Electric Company will install an electric light plant.

NEW ORLEANS, LA.—It is stated that the Consumers' Electric Company has purchased a site on Rampart and Bienville Streets for a power plant.

VIDALIA, LA.—The electric light plant which has been operated here by a New Orleans firm has been turned over to the municipality for $15,000, bonds for this amount having been voted last year. The plant cost $10,000.

BANGOR, ME.—The Underwriters' Light, Heat & Power Company, of Bangor, with $3,000,000 capital, has been incorporated under the laws of Maine.

TURNERS FALLS, MASS.—At a recent annual meeting of the Turners Falls Company is was voted to increase the capital from $300,000 to $600,000 and continue the work of improving the power and building an electric plant. C. T. Crocker is president.

MARSHALL, MICH.—The old Brush arc machines in the municipal lighting plant in this place will probably be taken out this summer, and the service changed over to the series alternating system. Mr. P. S. Joy is superintendent.

PENTWATER, MICH.—A contract has been entered into between the village and the Oceana Electric Company by which the company will install equipment to furnish 20 arc lights for the village and current for all private consumers at 50 cents per incandescent 32-cp lamp. Arc lights are to be of 1000-cp, and to cost $75 each per month for the 20 lamps.

WHITE BEAR, MINN.—The White Bear Electric Company has increased its capital stock from $10,000 to $25,000.

ROCHESTER, MINN.—A company may be organized to develop electric power from the water power at Jarrett. F. G. Colburn is owner.

MONTEVIDEO, MINN.—It is stated that the Montevideo Electric Light & Power Company will push the work of developing Minnesota Falls.

LAKE CITY, MINN.—A new engine and dynamo are to be installed in the municipal lighting plant, and the system is to be changed to the alternating.

EDINA, MO.—The Edina Electric Light & Power Company has been sold to P. M. Peterson, of Rock Springs, Wyo., through the agency of the J. S. Maurer Company. Mr. Peterson expects to remodel this plant and will therefore be in the market for general electrical supplies.

DELTA, MISS.—The Delta Electric Light & Power Company announces that it will immediately begin the work of extending its electric railway to take in all parts of the city. The rails, etc., have already arrived.

LINCOLN, NEB.—Electric light bonds to the amount of $65,000 have been sold.

CLINTON, N. Y. A municipal lighting plant may be established here. The matter is being considered.

LOCKPORT, N. Y.—A contract has been entered into with the Lockport Gas & Electric Light Company for lighting the city for three years, beginning June 8, at $75 each for 300 arc lights.

MT. OLIVE, N. C.—Plans and estimates are being prepared for an electric light plant.

WEST MANSFIELD, OHIO.—The village of West Mansfield has sold $11,000 worth of bonds for the purpose of installing an electric light plant in the village. Contracts will be placed in the near future.

WARREN, OHIO.—Stockholders of the Warren Electric Light & Power Company are arranging to consolidate the company with the Warren Water Company. The company will be known as the Warren Water & Light Company.

TARENTUM, PA. The citizens have voted to issue $37,000 bonds for improvements to the lighting plant.

SHENANDOAH, PA.—The Shenandoah & Mahanoy City Light, Heat & Power Company has been incorporated, with a capital of $75,000. David Graham, of Mahanoy City, is president, and W. T. Lee, of Shenandoah, is treasurer.

WILLIAMSPORT, PA.—It is stated that the Citizens Electric Light Company, of this place, of which Mr. Jonas Fischer is the principal owner, contemplates the erection of large buildings on the river-front for manufacturing purposes, and the utilization of water power for the generation of electric power for lighting, etc. Mr. Fischer's idea is to furnish commercial lighting, but he will also bid for the city lighting.

NEWBERRY, S. C.—The question of improving the electric light plant at a cost of $5000 is under consideration by the Town Council.

COLUMBIA, TENN.—The Columbia Water & Light Company will add new equipment for supplying a day service.

TRACY CITY, TENN.—The Tracy City Electric Light & Power Company has been incorporated, with a capital of $5000, by Samuel and Henry Werner.

COLUMBUS, TEX.—An effort is being made towards the establishment of an electric power plant on the Colorado River at this place.

LEONARD, TEX.—The Electric Light & Power Company has been organized at Leonard with a capital stock of $15,000. W. C. Evans is one of the incorporators of the company.

SHERMAN, TEX.—The Sherman Gas & Electric Company has been organized at Sherman with a capital stock of $200,000. The incorporators of the company are J. F. Strickland, W. R. Brents and C. N. Roberts, of Sherman; R. B. Sticher, of Cleburne; Osie Goodwin, M. B. Templeton and J. L. Penn, of Waxahachie, Tex.

RICHMOND, VA.—It is said that the Chesapeake & Ohio Railroad will investigate the matter of establishing an electric plant at Richmond for the purpose of supplying light and power for its buildings in the city.

SNOHOMISH, WASH.—The plant of the Electric Light & Power Company was destroyed by fire May 26. The loss was about $6000.

WHEELING, W. VA.—The Mutual Electric & Machine Company contemplates the erection of a $100,000 factory at Glenova for the manufacture of electrical machinery and apparatus. Mr. H. S. Sands is president.

GUAYAMA, PORTO RICO.—Bids will be received June 18 by Fernando Lugo Vina, Mayor, for $140,000 bonds to be used for an electric light plant, reservoir mains, sewerage system paving, erecting city hall, market-house, and for other public work.

THE ELECTRIC RAILWAY.

BUENA VISTA, CAL.—The city has granted to the American Crude Rubber Company, of which F. R. Marsh is president, a franchise to build an electric railway through the city to the various hot springs and summer resorts, not only for the purpose of carrying passengers, but also for carrying ore.

FORT COLLINS, COL.—The City Council has approved the ordinance granting electric street railway franchises to the Northern Colorado Electric Railway Company.

CHICAGO, ILL.—A special meeting of the stockholders of the South Side Elevated has been called for August 9, to authorize an issue of $8,000,000 4½ per cent bonds.

VEEDERSBURG, IND.—The survey is now being made for the proposed Veedersburg & Rockville Electric Railway.

INDIANAPOLIS, IND.—The Fidelity Construction Company, of Detroit, has commenced work near Noblesville, 25 miles from this city, on the construction of the Fort Wayne & Southeastern Railroad.

NEW CASTLE, IND.—Michael Gleason, of Richmond, reports that New York capitalists have consented to finance the Richmond & Northwestern Traction Company, in which he is interested. The line will run from New Castle to Richmond by way of Hagerstown.

MONTPELIER, IND.—The Portland, Montpelier, Warren & Huntington Electric Railway Company has filed articles of incorporation with the Secretary of State. The initial capital stock is $15,000. The directors are James West, Levi Hoffman and Scott Mills. The principal office will be in Montpelier.

FT. WAYNE, IND.—A syndicate of Eastern capitalists, headed by Thomas Wanamaker, of Philadelphia, has purchased the Fort Wayne Electric Light & Power Company's plant, and also the Fort Wayne traction lines and the bulk of the interurban connections which have recently been merged under the name of the Fort Wayne & Wabash Valley Traction Company.

ANGOLA, IND.—The stockholders of the Jackson & Fort Wayne Interurban Railway Company held a meeting here a few days ago and passed a resolution declaring that the road be built, equipped and operated at the earliest possible date, and authorized the directors to issue bonds to the amount of $4,000,000 for that purpose. John H. Roberts is president, and Joseph McKee, secretary.

OSKALOOSA, IA.—The Mahaska Construction Company has been formed to build an electric railway to Beacon and Buxton.

CRESTON, IA.—A company has been formed to build an electric interurban railway to Des Moines. Richard Brown, of Creston, is secretary.

NEW ORLEANS, LA.—The suit of the State of Louisiana against the New Orleans Railways Company involving the validity of the amalgamation of several street railway lines into one system has been reset for trial Nov. 7, at the request of the attorneys for the railways company.

SAGINAW, MICH.—T. E. Tarsney and T. G. Sullivan have asked for a receiver for the Detroit, Flint & Saginaw Railway, the newly projected interurban road from this city, which got as far as Bridgeport, 7 miles distant.

BELLEVILLE, MICH.—Citizens of this place and vicinity held recently a meeting to consider the project of building an electric railway from Detroit to Adrian, passing through this place. George William Moore, of Detroit, was present and addressed the meeting. An executive committee of seven was appointed. The proposed road is to be built on private right of way.

ROCHESTER, N. Y.—The Rochester & Eastern Rapid Railway Company has filed with the Secretary of State a certificate of increase of capital from $500,000 to $1,500,000.

NEW YORK, N. Y.—The Railroad Commissioners are said to have directed the Interborough Rapid Transit Company to equip all of its cars with fire extinguishers placed so as to be accessible in case of accident.

ROSLYN, N. Y.—Representatives of the Central Long Island Electric Light & Railroad Company are busily engaged in getting consents of property owners along the line of the proposed route of the company, between Huntington and Roslyn. All contracts have been signed for the construction of the line.

CHARLOTTE, N. C.—The new Jim Crow car law of Mississippi went into effect June 1, providing separate compartments in street cars for the races.

CARROLLTON, OHIO.—A. H. Snively is obtaining right of way through this district for a proposed electric railway from Canton to Steubenville.

CONNEAUT, OHIO.—George J. Chapman, chief promoter of the proposed Conneaut & Southern Railway, claims that Eastern capitalists will finance the project and that the prospects are good for the early commencement of construction work.

ZANESVILLE, OHIO.—The Southeastern Ohio Railway, Light & Power Company is advertising for bids for the construction of the roadbed of its line from South Zanesville to Crooksville; bids to be opened July 2. M. W. Hissey is president of the company.

XENIA, OHIO.—It is reported on good authority that the American Railways Company, which owns one of the local lines in Dayton, has secured control of the Dayton & Xenia Traction Company, which operates two distinct lines between Dayton and Xenia and a spur line to Spring Valley. It is stated that the Xenia line will be extended to Washington C. H., and the Spring Valley line to Wilmington.

NORWALK, OHIO.—The Sandusky, Norwalk & Mansfield Electric Railway Company has increased its capital stock to $600,000. Officers have been elected as follows: S. S. Burtsfield, of Toledo, president; Sherman Culp, of Norwalk, vice-president; B. B. Avery, of Cleveland, secretary-treasurer. The company has succeeded in financing its project for a line from Norwalk to Mansfield. C. F. Gilbert, of Cleveland, will be chief engineer in charge of construction work.

ST. CATHARINES, ONT.—The rate payers are to vote on June 22 on a by-law to approve the subscription of $20,000 worth of stock in Niagara, Queenston & St. Catharines Railway Company, which will build an electric railway from St. Catharines to Niagara-on-the-Lake and thence along the banks of the Niagara River to Queenston. W. A. Mittleberger is secretary-treasurer.

PORTLAND, ORE.—The Portland & St. Johns Railway Company has received a franchise to extend its line to St. Johns.

LEBANON, PA.—The Philadelphia, Lancaster & Harrisburg Passenger Railway Company has decided to extend its lines to Lebanon.

WEST BETHLEHEM, PA.—The Town Council has passed the ordinance granting a franchise to the Hanover Central Electric Railway Company.

LEBANON, PA.—Philadelphia capitalists, headed by Chas. S. Lurch, will build the proposed Palmyra, Valley Glen & Grantville Electric Railway this summer. A power house will be built at Valley Glen Park, which will be fitted up as a summer resort.

WEST CHESTER, PA.—The charter for the Oxford, Cochranville & Parkesburg Electric Railway has been filed. The entire distance covered is about 14 miles. Thomas E. O'Connell, of West Chester, is the principal promoter of the enterprise. The capital is given at $84,000.

HOUSTON, TEX.—The street car employes of the Houston Electric Company went on strike June 2.

SAN ANTONIO, TEX.—The shareholders of the Southern Light & Traction Company voted on June 2 to reduce the capital stock from $2,500,000, par of shares $100, to $2,500 par of shares 10 cents. The entire stock is owned by the American Light & Traction Company.

McKINNEY, TEX.—The survey for the proposed interurban electric railway between this place and Bonham by way of Blue Ridge and Denton has been commenced. It is stated that most of the right of way of the proposed line has been secured. R. Woodson, of St. Louis, Mo., is associated with local capitalists in the promotion of the enterprise. Jesse Shain, of McKinney, who is interested, can give information.

NEW INDUSTRIAL COMPANIES.

THE ELECTRICAL CONSTRUCTION COMPANY, of San Diego, Cal., has been incorporated to manufacture and deal in electric and gas fixtures. The capitalization is $10,000.

THE PENN ELECTRIC EQUIPMENT COMPANY, of Camden, N. J., has been incorporated by B. L. Cater, G. C. Rawson and W. C. Rawson, the capital stock being $20,000.

THE NATIONAL BATTERY COMPANY, of Buffalo, N. Y., has been incorporated with a capital stock of $500,000, the incorporators being R. L. Coleman, W. H. Miller and W. L. Hodges, of New York.

THE GENERAL RAILWAY SIGNAL COMPANY, of Gates, Monroe County, N. Y., has been incorporated with the Secretary of State, with a capital of $5,000,000, of which $2,000,000 is 6% cumulative preferred stock. The directors include Fredk. Cook, of Rochester, Geo. D. Morgan, of Buffalo, and other western New Yorkers.

LEGAL.

RIGHT TO OCCUPY TURNPIKE.—In an appeal by Brown vs. Radnor Township Electric Light Company, the Supreme Court of Pennsylvania has sustained the lower court as follows: 1. Under Act May 8, 1889 (P. L. 136), providing for the incorporation of electric light companies, and section 2, authorizing such corporations to supply light, heat and power to the public in the borough, town, city, or district where it may be located, such a company is not restricted by the word "district" to a division of a city or borough, but may be incorporated in a township. 2. Under Act May 8, 1889 (P. L. 136), providing that every electric light company shall have power to erect the necessary buildings and apparatus, with a right to enter upon any public street, lane, alley, or highway to inspect, alter, and repair its system of distribution, an electric light company has power to enter upon the bed of a turnpike road and erect its poles and string its wires, notwithstanding the objection of abutting owners owning the fee in the bed of the road.

SALE OF ELECTRICAL APPARATUS.—An appeal before the Court of Appeals of New York, settled in favor of the General Electric Company against the National Contracting Company, is of interest, as to sale of apparatus. The decision is summed up as follows: 1. A written contract of sale may be modified as to time of performance by consent of the parties, notwithstanding the contract provides that no modification thereof shall be binding unless in writing. 2. Where a written contract of sale, providing that no modification thereof should be binding unless in writing, was, by consent of the parties, and for their convenience, modified as to the time of performance, and defendant permitted plaintiff to go on with the work after the time specified in the contract, he is stopped from setting up the defense of non-performance as to time. 3. An exception by defendant to certain testimony admitted in proceedings before a referee before the pleadings were amended is not available on appeal where the amendment obviated all objection to the testimony. 4. The seller of machinery to be delivered and installed at a specified time may, on refusal of the purchaser to accept or pay for the same, sell it at public auction, and recover from the original purchaser the price thereof, after deducting the amount received at the auction sale and the cost of installing the machinery, together with interest on such balance from the time of the purchaser's default. The apparatus referred to was for the Hudson River Water Power Company at Spier Falls.

CONTROVERSY AS TO SUBWAY.—The Court of Appeals of the State of New York has decided in the suit of the Western Union Telegraph Co. vs. Electric Light & Power Co. of Syracuse, as to relative subway rights. The original telegraph subway was 16 in. high and 9 in. wide, a few feet below the street surface, with six wooden ducts. The electric light subway, under a later franchise, was 26 in. wide by 17 in. high in close juxtaposition to the other. The Appeals Court held: 1. Where plaintiff sued to restrain defendant from maintaining a street subway in close proximity to plaintiff's subway, previously constructed, and to compel defendant to remove its lines therefrom, but did not allege in its complaint that defendant was insolvent or that a multiplicity of suits would result, a judgment denying the injunction, but directing that defendant should indemnify plaintiff for any injuries it might suffer through the trespass by the execution of a bond, was erroneous, as an adjudication that an action in equity was unnecessary, as plaintiff had a sufficient remedy at law. 2. Where the common council of a city granted a corporation a right to construct a subway below the surface of the street, and provided that such franchise should not be deemed to give such company any exclusive right to the street for such subway, and reserved to the city all rights not spectfically given, such company cannot object because the city thereafter gave another company a right to locate its subway so close to plaintiff's subway as to cause expense in making repairs, if such subsequent location was not an unreasonable interference with plaintiff's rights.

RIVAL LIGHTING COMPANIES.—The Supreme Court of Kansas had before it recently an appeal on error from a district court in the action of the Keene syndicate against the Wichita Gas, Electric Light & Power Company to recover rent due under a lease. On the 14th day of May, 1897, the Wichita Electric Railway & Light Company, a corporation under the laws of Kansas, with its place of business at the city of Wichita, entered into a contract or lease in writing with the Wichita Gas, Electric Light & Power Company, a corporation under the laws of Kansas, with its place of business at the city of Wichita. By the terms of the contract or lease the former leased to the latter for a period of 10 years, at an annual rental of $3000, payable semi-annually, certain machinery and appliances, in the city of Wichita, adapted to and used by the lessor for the purpose of generating electricity for light, heat and power. On the 20th day of March, 1900, the Keene Syndicate, a corporation, purchased of the lessor, the Wichita Electric Railway & Light Company, the property included in and covered by said lease, and also its interest in said lease, taking a written assignment thereof. The lessee, the Wichita Gas, Electric Light & Power Company, being in default of three years' rent in August, 1900, the Keene Syndicate, as assigree of the Wichita Electric Railway & Light Company, commenced its action in the district court of Sedgwick County to recover the rent, the amount claimed due it from the lessee. The syllabus of its decision against the lease by the Supreme Court is as follows: "A corporation, engaged in the business of generating and furnishing electricity for public and private use, leased to a rival corporation in the city, for a period of 10 years, machinery and appliances used in generating electricity, obligating itself by the provisions of said lease not to engage in the business of furnishing electric light and power to public or private consumers in the city during said period, and not to dispose of any of its property, machinery, or appliances retained by it for producing or generating in said city electric light and power. Held, in an action on said lease to recover rents from the lessee, that the lease is in contravention of public policy, and that no action to recover rents can be maintained thereon by the lessor or its assignee."

TELEPHONE LINE IN HIGHWAY.—The Supreme Court of Kansas in the suit of McCann vs. the Johnson County Telephone Company has decided that the construction and maintenance of a telephone line upon a rural highway is not an additional servitude for which compensation must be made to the owner of the land over which the highway is laid. The complainant was a farmer. In constructing a telephone line the Johnson County Telephone Company planted poles along the highway in front of his farm. The poles were placed near the hedge fence on the land dividing the farm from the highway, and were so located as to interfere with the trimming of the hedge, and also with the cutting of the grass and weeds on the roadside. He brought an action of injunction, alleging that the company had not obtained his consent to plant telephone poles on the highway opposite his farm, that his interest as the owner of the fee had not been conveyed, condemned, nor otherwise appropriated; and that no compensation had been paid to him for the proposed use. A temporary order, restraining the company from placing poles opposite the plaintiff's farm was issued, but on the final hearing it was dissolved, and a perpetual injunction was denied. The question presented in this appeal was, as at the first hearing of the proceeding, whether the telephone company might occupy the highway in front of McCann's farm without obtaining his consent or paying him compensation for the right. Was this a contemplated use when the road was established, or does it constitute an additional servitude? The court quoted with approval the decision in Cater vs. Northwestern Telephone Exchange Co.: "The methods of using public highways expanded with the growth of civilization until to-day our urban highways are developed to a variety of uses not known in former times, and never dreamed of by the owners of the soil when the public easement was acquired. Hence it has become settled law that the easement is not limited to the particular methods of use in vogue when the easement was acquired, but includes all new and improved methods, the utility and general convenience of which may afterward be discovered and developed in aid of the general purpose for which highways are designed; and it is not material that these new and improved methods of use were not contemplated by the owner of the land when the easement was acquired, and are more onerous to him than those then in use." The court held that the construction and maintenance of a telephone line on a country highway did not impose an additional servitude upon it, but was to be regarded more as a newly discovered method of using an old public easement.

OBITUARY.

E. B. CHANDLER, who was the first city electrician of Chicago, and afterwards western agent of the Gamewell Fire Alarm Telegraph Company, died at his home in Chicago, June 7. He was born in Hartford, N. Y., in 1838.

MR. W. A. VAIL.—William A. Vail, assistant general manager of the Northwestern Telephone Company, died of pneumonia at his home in Minneapolis on June 4. Deceased was well known in telephone circles throughout the country, especially in New York, where he was located for several years. Mr. Vail was 45 years of age.

PERSONAL.

MR. CHAS. R. GUERTLER, of the Engineering Company of America, is making an examination of the route for the proposed Roanoke and Mt. Airy electric railroad.

MR. DONALD MURRAY has reprinted in pamphlet form from the *Elektrotechnische Zeitschrift*, the elaborate article recently published on his automatic telegraphic system, written by Herr A. Kraatz. It is an exhaustive description.

DR. CHARLES BASKERVILLE, who attracted considerable attention a few months ago by "splitting" thorium into two elements, which were named carolinium and berzelium, has come to New York as head of the department of chemistry in the College of the City of New York.

MR. SAMUEL INSULL, president of the Chicago Edison Company, who has been taking a holiday with his family in England and on the Continent for some weeks past, has just returned, feeling much better for the change. Part of the stay in England was occupied with automobile tours.

MR. WALLACE C. JOHNSON, consulting engineer of the Niagara Falls Hydraulic Power & Mfg. Company, has been engaged by the Sientere Viva Mining Company, Bluefields, Nicaragua, to draw out plans and specifications, as well as to construct and equip extensive electrical power development and transmission systems in the locality of Bluefields.

MR. G. MARCONI has returned again on the Cunarder *Campania*, the trip being made with the object of starting up a regular newspaper service on the line by wireless. The newspaper proved very successful, plenty of news being received and printed on the trip. The *Cunard Daily Bulletin* is an excellent little sheet, and ought to prove a good journalistic property.

MR. ROBERT McF. DOBLE, of San Francisco, consulting and supervising engineer, making a specialty of hydro-electric power developments and long distance power transmission, announces that he has become identified with the Abner Doble Company, engineers and manufacturers of tangential water wheels with needle regulating nozzles. His offices will be at 417 Rialto Building, San Francisco.

MR. T. DURMAN, representing W. S. Laycock, Ltd., the well-known government and railway stores contractors of Sheffield, England, is on a visit to this country after about ten years' absence. He is very much pleased and surprised at the growth in that period. He is proceeding from New York to St. Louis, where he expects to devote some time to the Transportation Building. He will also visit some of the Western cities.

MR. U. N. BETHELL, vice-president and general manager of the New York Telephone Company, on June 3 gave an interesting talk before the Men's Club of the Methodist Church, Montclair, N. J., taking for his subject the business and social aspects of the telephone. Mr. Bethell's thorough knowledge of his subject and his masterly manner of presenting his facts insured deep and thoughtful attention from his audience.

MR. GEO. A. DAMON and Miss Henrietta B. Diller, daughter of Mr. and Mrs. Henry B. Diller, of Chicago, were married at Chicago, June 8. Mr. Damon is the managing engineer of the Arnold Electric Power Station Company, and has many friends and admirers among the electrical engineering profession in Chicago, where he is very prominent in technical circles. His recent paper on the earnings of electrical engineers attracted universal attention, and embodied a large amount of valuable data.

W. K. VANDERBILT, JR., is busily engaged studying electricity, says the *New York Times*, and getting informed on the technical points of railroad administration. The young millionaire is working in the department of Mr. W. J. Wilgus, fourth vice-president of the New York Central. He gets to his office every morning before 10 o'clock and leaves about 4. P. M. for his yacht, anchored at the foot of East Forty-second Street.

MR. W. C. GOTSHALL.—A few weeks ago Mr. W. C. Gotshall, president of the New York & Port Chester Railroad Company, while driving an automobile through one of the east side sections of New York City, with his wife, was attacked by a gang of roughs, who stoned the vehicle. Mrs. Gotshall was severely wounded on the head and her life was despaired of. We are glad to announce that she is now much better and will be able to be up and about within the next week. Meantime the hoodlums appear to have escaped punishment.

MR. S. S. FOLWELL, manager of the street railway department of G. D. Peters & Company, London, was in New York this week winding up a visit of some two months in this country. Mr. Folwell states that the business outlook on the other side of the Atlantic is good. G. D. Peters & Company have just secured the contracts from the Underground Electric Roads, of London, Ltd., for the car seats and blinds for the 420 new electric cars which will shortly be used in the District Underground Railway. This is the old original London Underground which is now being electrified. The seats are "Hale & Kilburn," similar to the seats used on the Manhattan Elevated Railway.

Trade Notes.

THE TWYFORD MOTOR CAR COMPANY, Brookville, Pa., is erecting a two-story building, 50x200 feet, and has ordered all the machinery for its equipment.

W. M. SHEEHAN & COMPANY, 136 Liberty Street, N. Y. City, have issued catalogue No. 25, a neat little pamphlet devoted to direct and alternating current fan motors of all styles of application. These are all illustrated, and sizes and prices are given.

DIXON'S GRAPHITE CUP GREASES are the subject of a neat little special pamphlet issued by the Joseph Dixon Crucible Company, of Jersey City, N. J., and devoted to a discussion of this interesting subject, as well as giving details about the varieties, etc.

"NOSCRU" PUSH BUTTONS.—The Sarco Company, 906 Sixth Avenue, New York, manufacturer and owner of several electrical appliances operated without screws, particularly the "Noscru" push button, reports that where dealers are running short of midget push buttons they are ordering the "Noscru" in preference to others having screw connections. Some of these devices have been recently described and illustrated in these columns.

THE NERNST LAMP.—A very useful and interesting, as well as attractive little pamphlet has just been issued by the Nernst Lamp Company, of Pittsburg, entitled, "The Value and Utility of the Nernst Lamp to the Central Station." It is not only a brisk discussion of the subject, in cogent terms, but embraces considerable data. Our central station readers ought to secure a copy.

THE CENTRAL ELECTRIC COMPANY, Chicago, announces the fact that it is prepared to furnish D. & W. fuses and blocks, up to 800 amperes in both 250 and 500 volts. The company is also authority for the statement that the demand for D. & W. material is still increasing and says that the most fortunate thing about it is that a customer who tries D. & W.'s is sure to continue using them.

NATIONAL-ACME.—The National-Acme Manufacturing Company, of Cleveland, Ohio, announces the opening of a New York office at 220 Broadway, in charge of Mr. R. A. Scranton, manager, to attend to business in this part of the world in its Acme automatic multiple spindle screw machines, screw slotters, cap screws, set screws, etc. Local orders and inquiries will receive prompt attention from Mr. Scranton.

THE EMERSON ELECTRIC MFG. COMPANY, of St. Louis, reports that prompt shipments can be made of Emerson desk and ceiling fans for any regular voltage or frequency. This company, as usual, is carrying a well-assorted stock in New York City, as well as in St. Louis, and Eastern customers can depend upon receiving prompt service from New York City. Over twenty styles are regularly carried in stock.

ELECTROLYTE FOR STORAGE BATTERIES.—The Franklin H. Kalbfleisch Company, New York, the well-known manufacturing chemist, has just issued a little pamphlet giving some extracts from publications of various concerns, and the published works of authorities as to the importance of using pure chemicals in storage batteries. All of the authors are unanimous on this point. The Kalbfleisch Company guarantees its electrolyte to be made from pure Sicily brimstone sulphuric acid and distilled water.

THE CRESCENT COMPANY, of Chicago, has shown its faith in the time switch as the coming way for handling show window signs and hall lights by taking the exclusive Western agency for the Crescent time switch. To get this agency, it had to contract for an immense number of these machines. The hustling abilities of this company are a guarantee that they will be distributed. This device has met with great favor on account of its low price, simplicity and positive action. Bulletin 205 fully describes it.

EWING-MERKLE ELECTRIC COMPANY, of St. Louis, Mo., has issued an illuminated and indexed map of the World's Fair grounds and the pike, which is remarkable in its completeness and convenience. It is 8x12 inches in size and folds up into a neat envelope, so that it can be easily carried in the vest pocket. It shows the location of every building and every feature on the grounds, and the index enables one to find instantly the location sought. A copy will be given free to anyone who applies for it either personally or by mail.

MESSRS. JORDAN BROS., 58 Fulton Street, New York, have brought out an ingenious exhaust and ventilating device which is easily and readily installed. It consists of a separate window sash which is screwed on the inside of the window case. In the window pane is cut out a circular hole of the same diameter as the fan guard, and an electrically-driven fan is mounted on a bracket so that it can be placed in front of the aperture in the window and moved away from it when it is desired to close the opening, which is done by raising the regular window sash. The fan is then swung back against the wall. This device is recommended for offices, private residences, churches, clubs, yachts, restaurants, etc. It keeps the air pure and clean in winter without draft or lowering the temperature of the room, and in the summer doing an equally valuable service either as an exhaust or suction fan.

NILES-BEMENT-POND COMPANY.—The May bulletin of this company has some very interesting data in its twelve handsome quarto pages. The first page shows a new 10-foot mill for use on high power tool steel, and another fine tool shown, as well as described is the 3 by 36-inch turret lathe, Pratt-Whitney type. A striking tool also is that driven by electric motor, a 108-inch Bement lathe, which swings 109½ inches over the bed and 74 inches over the carriages. A controller handle is provided for each carriage, so that the speed of the lathe can be conveniently controlled by the operator without change of position. There are also shown a 90-inch driving wheel lathe, a No. 11 vertical milling machine, hydraulic angle and bar shear and splitting shear. A very interesting view is that of a horizontal boring, drilling and milling machine on a milling job on the base of a casting too large to go through the planer.

A STERLING INVITATION.—Mr. W. E. Doolittle, president of the Sterling Electric Company, of Lafayette, Ind., has issued the following hearty circular of invitation: "The Indiana State Telephone Convention has been called to meet in Lafayette, June 28 and 29. As this is the home of the Sterling Electric Company we shall use every effort to make this the largest state convention upon record. From assurances already given, we believe we can state that there will be from 200 to 250 representatives of operating companies present. The headquarters will be at the Hotel Lahr. We have provided as entertainment for all; street-car ride, vaudeville show at Tecumseh Trail (a summer garden), inspection of Purdue University, boat ride, banquet at the German National Park, and a general good time. We wish to extend our invitation in addition to the notice of the Association, requesting that you be present. We assure you that you will be accorded every privilege that we have ourselves and will be treated with all fairness. We shall at least endeavor to make the Convention a pleasant one and sincerely hope that you will make it a profitable one. Give the matter your early consideration and arrange to be represented. Would suggest that you make an early reservation, and would be pleased if you would notify us the number of people you will have present so that it will assist us in arranging for the entertainment."

THE ELECTRIC SUPPLY COMPANY, of Savannah, Ga., is now doing business at No. 38-40 Drayton Street, with a branch store at No. 309 Bull Street, devoted almost exclusively to the automobile business. This company is now recognized as a factor in the electrical supply business of the South. Its customers are found all throughout the States of Georgia, Florida, Alabama, South Carolina and Texas. Its prominent Southern location and its fine new stores and sales rooms with increased shipping facilities, enable it to handle its fast increasing business with much better satisfaction to customers. It has quite a line of first-class specialties, such as Circular Loom flexible conduit, Fostoria incandescent lamps, Crocker-Wheeler motors and dynamos, and all standard makes of electric ceiling and desk fans. It also carries a large stock of general supplies and is increasing its line constantly by putting in new specialties as fast as perfected. This company's construction department has secured contracts since June 1 amounting to nearly $50,000. This covers the wiring of government buildings at Fort Dade, Fort De Soto and Fort Barrancas, Fla., and Fort Screven, Ga.; the Jacksonville, Fla., Post Office annex, and the Savannah, Ga., City Hall Building. This company has just finished wiring the Central of Georgia Railway Co.'s office building at Atlanta, Ga., and installing chandeliers in the Germania Bank Building at Savannah, Ga., and is now wiring the County Court House at Washington, Ga., and installing the Sandersville, Ga., electric light plant. The company's new venture—its automobile department—is meeting with great success, the business done the first two months having exceeded its most sanguine expectations.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED JUNE 7, 1904.

[Conducted by Rosenbaum & Stockbridge, Patent Attys., 140 Nassau St., N. Y.]

761,465. ELECTRICAL APPLIANCE; Philip H. Fielding, New York, N. Y. App. filed Aug. 26, 1903. A receptacle adapted for stringing lamps outside, it having the shape of a yoke to be saddled over a guy-wire and having means for making weather-proof connection with conductors and with the lamps attached to it.

761,637. TROLLEY GUARD; Linwood B. Aikens, Rockledge, Fla. App. filed March 24, 1904. A roller is mounted eccentrically on each side of the trolley wheel; when the wire leaves the wheel and falls upon a roller, the latter is caused to rotate and lift the wire to a position where it will again fall into the groove of the wheel.

761,641 and 761,642. EXCITING FLUID FOR ELECTRICAL BATTERIES; George F. Atwood, Wakefield, Mass. App. filed Oct. 3, 1903. (See page 1163.)

761,675. ELECTRIC CUT OUT; William J. Hartwig, Detroit, Mich. App. filed Feb. 29, 1904. Details of an inclosed fuse.

761,682. CONTINUOUS CURRENT DYNAMO; Emile J. Javaux and Alfred L. Barbou, Paris, France. App. filed Jan. 28, 1903. Iron rods are moved to a greater or lesser distance into passages in the pole pieces to interpose more or less iron in the magnetic circuit.

761,694. ELECTRIC RAILWAY SYSTEM; Charles H. Murphy, Scranton, Pa. App. filed Sept. 1, 1903. Details of a switching device for energizing sections of a third rail as the train traverses it.

761,743. ELECTRIC SWITCH FOR HIGH POTENTIALS; Gilbert Wright, Pittsfield, Mass. App. filed Sept. 24, 1903. The contracting surfaces are formed with corresponding inclines which come together upon the closing of the circuit, but which are not in contact while the circuit is held closed; the circuit is broken upon the same inclined surfaces, which therefore receive the effect of the arc and shield the main contact surfaces therefrom.

761,744. SWITCH CONTACT; Gilbert Wright, Pittsfield, Mass. App. filed Oct. 14, 1903. A modification of the preceding patent.

761,745. SWITCH FOR ELECTRIC CIRCUITS; Gilbert Wright, Pittsfield, Mass. App. filed Nov. 30, 1903. A further modification of 761,743 involving an oil switch.

761,748. CIRCUIT BREAKER; John R. Anderson, Jr., Pittsfield, Mass. App. filed Sept. 12, 1903. A device for adjusting finely the position of the magnet core with respect to the armature upon which it acts.

761,760. INSULATOR; Cummings C. Chesney, Pittsfield, Mass. App. filed

Aug. 8, 1903. A number of petticoats telescoped into one another with their edges of such shape and size as to be equidistant at all points.

761,776. CIRCUIT BREAKER; William J. Lloyd, Pittsfield, Mass. App. filed Aug. 19, 1903. The retractile spring on the armature is so disposed that its force diminishes as the armature is moved by the attraction of the magnet.

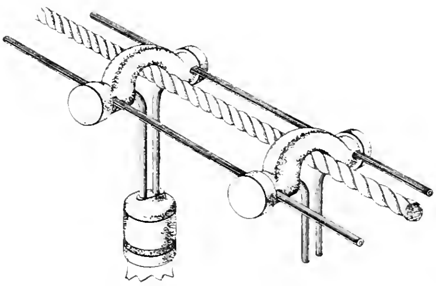
761,814. COMBINED INSULATOR AND FUSE BOX; Aaron Bearse, Syracuse, N. Y. App. filed Aug. 26, 1903. A knob insulator containing a chamber above the end of the pin for a fuse.

761,848. TROLLEY SIGNAL; Charles H. Morse, Cambridge, Mass. App. filed June 27, 1901. Details.

761,853. ELECTRIC RAILWAY SIGNAL; Robert J. Sheehy, New York, N. Y. App. filed Sept. 9, 1902. The current for operating signals in a block system is taken from the third rail power current by the car and transferred to another rail alongside the third rail; the latter is divided into sections and the signals are located in the cab of the car and are operated by arms at the roadside which are thrown into position automatically.

761,875. OVERHEAD ELECTRIC CARRIER; Charles M. Clark, South Orange, N. J. App. filed Nov. 24, 1902. The motor in a telpher system can be reversed and the bucket dumped at any predetermined point.

761,876. MEANS FOR REVERSING ELECTRIC MOTORS; Charles M. Clark, South Orange, N. J. App. filed Dec. 10, 1902. In a system similar to that previously described the breaking of the circuit through the motor throws a reversing switch, and upon a renewal of the current the parts are again put in position to reverse the motor.



761,405.—Electrical Appliance.

761,877. INSULATING BLOCK FOR ELECTRIC CONDUCTORS; Charles M. Clark, South Orange, N. J. App. filed July 7, 1903. Details of an insulating block used in the two systems preceding.

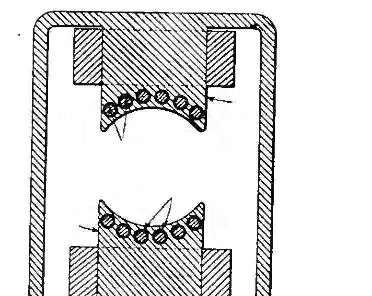
761,884. TELPHER; Henry M. Harding, New York, N. Y. App. filed Dec. 3, 1902. Means for regulating the lowering and hoisting of the bucket and means by which the circuit through the motor will be automatically broken and the telpher returned to its starting place.

761,895. SYSTEM OF ELECTRICAL DISTRIBUTION AND CONTROL; Lamar Lyndon, New York, N. Y. App. filed Dec. 15, 1903. In a system of distribution where current is generated from a car axle, means are provided for bringing the generator wholly to rest under conditions requiring such action.

761,917. TELEGRAPH TRANSMITTER; Willis J. Roussel, New Orleans, La. App. filed Feb. 11, 1903. The movement of a key in a key-board rotates a disk through one turn and brings metallic segments in the surface of the disk, corresponding to Morse characters, successively into contact with a finger trailing thereon.

761,920. ELECTRIC FURNACE; Charles Prosper Eugene Schneider, Le Creusot, France. App. filed Oct. 12, 1903. (See page 1163.)

761,928. MEANS FOR MOVABLY CONTACTING ELECTRICAL CONDUCTORS; Frederick G. Walker, Cleveland, Ohio. App. filed Aug. 12,



761,682.—Continuous Current Dynamo.

1903. Two trolley wheels placed at an angle with their rims together to form a single groove for the wire.

761,971. APPARATUS FOR GENERATING ELECTRICITY; Andrew C. Kloman, Pittsburg, Pa. App. filed Sept. 18, 1903. In a thermal generator means for simultaneously heating and cooling different parts thereof and for reversing the conditions so as to simultaneously cool the heated portion and heat the cool portion.

761,985. ROCKER RING FOR ELECTRICAL MACHINES; Edson R. Norris, Wilkinsburg, Pa. App. filed Sept. 16, 1903. A clamping device for a split ring consisting of a loop carried at one end of the ring and adapted to engage an inclined surface on the other and to be held in position by a set screw.

761,987. RAILWAY TRACK CURRENT CONTROLLER; Alfred Oesterreicher, Vienna, Austria-Hungary. App. filed May 28, 1903. A short length of rail held by a spring against the side of the track rail, to be moved laterally by the flange of the car wheel and thus close a signal circuit.

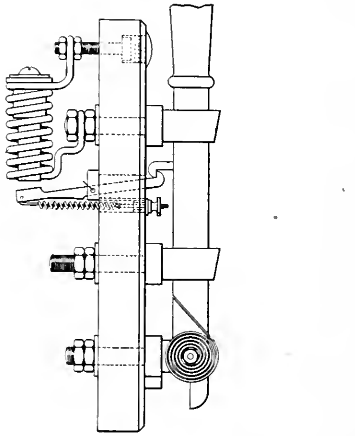
762,009. AUTOMATIC BLOCK SIGNALLING SYSTEM; Herbert B. Taylor, Newark, N. J. App. filed Oct. 14, 1903. Details.

762,030. INCANDESCENT LAMP; Samuel E. Doane, Cleveland, Ohio. App. filed Dec. 12, 1903. Certain kinds of metal have the same coefficient of expansion as glass and which could not heretofore be used for leading-in wires, on account of oxidizing and permitting leakage, are made available by plating them with an inoxidizable metal.

762,034. ELECTRIC SWITCH FOR MOTOR CARRIAGES; Henry Folger, West Somerville, Mass. App. filed Dec. 18, 1903. The handle of an ordinary three-point switch is made readily detachable for the purpose of disabling the switch.

762,074. BRUSH HOLDER; Emil S. Lueth, Baraboo, and Charles D. Knight, Milwaukee, Wis. App. filed March 21, 1904. An eccentric clamp for holding the torsion spring at any degree of tension.

762,105. ELECTRIC SEMAPHORE SIGNALING MECHANISM; Bruno O. Wagner, Amsterdam, N. Y. App. filed May 12, 1903. Details.



761,776.—Circuit Breaker.

762,111. ELECTRICALLY CONDUCTIVE COIL AND METHOD OF CONSTRUCTING SAME; Vincent G. Apple, Dayton, Ohio. App. filed Sept. 21, 1903. The layers between which the higher differences of potential exist are separated by thicker insulation than the other layers.

762,112. ELECTRICALLY CONDUCTIVE COIL AND METHOD OF CONSTRUCTING SAME; Vincent G. Apple, Dayton, Ohio. App. filed Sept. 21, 1903. Ribbon conductors are wound upon the core simultaneously with strips of paper which are so laid as to furnish the necessary insulation between adjacent turns.

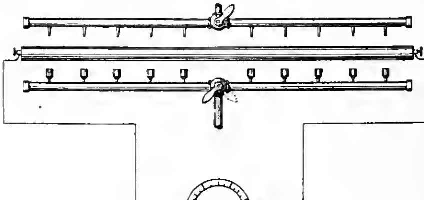
762,114. REGULATING DEVICE FOR ELECTRIC CIRCUITS; Malcolm H. Baker, East Liberty, Pa. App. filed June 25, 1902. The apparatus consists of a reactance device in series with the translating devices, the magnetic pull of the reactance device being opposed by a weight so regulated that the choking effect of the coil will vary automatically to compensate for changes in the resistance of the circuit.

762,125. ELECTRICAL TEMPERATURE ALARM; Joseph P. Bolton, Fresno, Cal. App. filed June 16, 1902. Contacts are adjustable in the path of movement of the needle of a thermometer.

762,141. ELECTRIC MACHINE; Niels A. Christensen, Milwaukee, Wis. App. filed April 8, 1901. A dynamo or motor is provided with a back-gearing device which is made adjustable for the purpose of using the machine on the floor, ceiling or wall.

762,192. SIGN RECEPTACLE; Clarence D. Platt, Bridgeport, Conn. App. filed Jan. 11, 1904. Details.

762,204. CIRCUIT BREAKER; Frank L. Sessions, Columbus, Ohio. App. filed June 16, 1902. Flat faced carbon contacts overlap each other, one of them sliding onto and off the other, the stationary plate being so mounted



761,971.—Apparatus for Generating Electricity.

as to assume a position which will ensure contact throughout the entire abutting surface.

762,215. SEARCHLIGHT; William O. Webber, Boston, Mass. App. filed Jan. 6, 1904. A traversing and make and break device whereby the light is caused to traverse intermittently over any desired arc and automatically reversed at each end of the traverse.

762,227. ANODE AND PROCESS OF MAKING SAME; Henry Blackman, New York, N. Y. App. filed Dec. 8, 1896. (See page 1163.)

762,229. EXPLOSIVE CARTRIDGE; Giovanni Cornara, Mantova, Italy. App. filed Dec. 31, 1897. (See page 1163.)

762,249. SAFETY STOP DEVICE FOR STATIONARY STEAM ENGINES; Charles A. Ott, Lincoln, R. I. App. filed Oct. 31, 1903. An electro magnet when energized operates a trip to move a controlling valve.

762,257. SYSTEM OF DISTRIBUTION; William M. Scott, Philadelphia, Pa. App. filed Aug. 18, 1903. A circuit breaking mechanism.

12,228. STORAGE-BATTERY ELECTRODE; Johannes von der Poppenburg, Charlottenburg, Germany. App. filed Nov. 12, 1903. (See page 1163.)

Electrical World and Engineer

THE CONSOLIDATION OF "THE ELECTRICAL WORLD" AND "ELECTRICAL ENGINEER."

CONTENTS.

THE POINT OF VIEW.

This is the season of the year when hundreds of young men, receiving the coveted diploma for which they have worked so long and hard, step out into the world as graduated electrical engineers and mechanical engineers; and are thus set apart and sealed to the professions toward which all their studies have been directed. It is a moment of anxiety as well as of congratulation for them and their relatives, but after all it is something that they cease to be merely part of the assimilative and destructive forces of the world and become portion of the influences and agencies that are to add to its stores and resources. Upon them in the next twenty-five years rests the virtual responsibility also for whatever advances American engineering is to make. Under these circumstances, it is not a little important that their training should have been broad, their culture deep, equal to and justifying alike their courage and their ambitions. How far this may be, no one can yet tell; but we do know how earnest and devoted has been the discharge of the professional functions under the exercise of which these young men have been shaped; and we can, therefore, but hope that the outlook is sunny for these latest exemplars in the noblest of professions.

At the commencement of Stevens last week, Mr. Walter C. Kerr, in a felicitous address to the graduating class, as noted elsewhere in these pages, took occasion to dwell upon the importance of the "point of view" for these young engineers. His sententious wisdom and shrewd epitomizing of an engineer's experience can but be heartily commended to every beginner. "To thine own self be true" is its keynote, and this is peculiarly applicable where the powers and instrumentalities to be dealt with are so tremendous there might easily be a temptation to think that the mechanism was all and everything and the man went for naught. Mr. Kerr, moreover, wants his engineer to be an "all around" engineer. That is sound advice and philosophy, and it may fitly be carried further with the suggestion, that the best object of all higher educational training is to create the "all around," manly man. It is for him that the world and society are looking, whatever be his differentiation as engineer, lawyer or physician.

As these young engineers emerge from the scholastic cloisters, one of the first inquiries is naturally as to the extent of the opportunities awaiting them. The current year may not perhaps be as insatiable in its demands for new blood as were the recent periods of gigantic activity, but there can be no doubt as to the work that awaits every one of them in the physical conquest of this continent or in the extension of American enterprise beyond the seas. In some ways the great consolidations may have restricted possibilities for the younger men, but that is very much open to doubt; and if it is actually so, it will prove but a temporary phase, for the next movement would be centrifugal and toward heterogeneity. Besides, there are many signs of newer days in electricity and mechanics. With radium on one side and the turbine and the gas engine on the other, no one knows yet in any degree what even these factors are cutting out in new work. As to cutting out also the Panama Canal is ahead, and it is not to be forgotten that the opening of the Suez Canal led to the swift, three-fold reconstruction of the mercantile fleets of the world, not to mention the navies. Hence, as we welcome the newly made engineers, we think it is quite safe to bid them let their "point of view" as to the future be a bright and cheerful one and then to bend all their energies toward making this world better and more habitable than they found it. If they do just this all the other things will be added unto them.

FOUCAULT PENDULUM SYSTEMS.

The article by Mr. Ernest K. Adams on page 1120 of this issue describes a variety of Foucault pendulum suspension that might be tried for maintaining the swings of the pendulum indefinitely. So far as we are aware no apparatus more perfect than the original Pantheon pendulum has ever been exhibited on a large scale. That classical experiment, although entirely satisfactory as a demonstration, was necessarily very crude, because no means were provided for maintaining the swing, and the period of time during which the swing could be self-sustained within the required limits was necessarily limited. Nowadays it should be possible to overcome this difficulty without great expense, and a self-supporting free pendulum would be a very pretty thing, worth going far to see. The suggestions for improvement offered by Mr. Adams in the present and in a previous article should, when experimentally sifted, result in an apparatus possessing all of the requirements for permanent public exhibition; and as an object lesson in the fundamental conceptions of motion, a view of such an apparatus would be highly instructive to the public—not only the untutored portion, but even those who have by rote learned the laws of planetary motion.

A. I. E. E. TRANSACTIONS.

The latest bound issue of the *Transactions* of the American Institute of Electrical Engineers is a slender volume which promises to be lost sight of on a shelf when sandwiched between its portly brothers. Another singularity about the volume is that while the title page describes the *Transactions* as covering the period from July 1 to December 31, 1902, the earliest date of transaction recorded is September 26, 1902. This miniature volume also puts an end to the further identity between the volume number and the age of the Institute. If the only reason for this odd volume is that the work of one administration should be separated from that of another, it would appear preferable to carry over matter corresponding to the beginning of an administration and include with it that of the remainder of the administration; or in case the extent of matter calls for two volumes, to divide it nearly equally to form two sections issued as "Parts" and carrying the same volume number. In any event, it does not seem desirable that the *Transactions* should continue to be issued in the form of a portly tome covering part of a year and a tiny complement covering the remainder. The prestige of the Institute rests very largely on its *Transactions*, and the form of these should not by their oddity give rise to adverse comment; and viewing the matter from the financial side, the cost of binding and distributing 3,000 or more copies of this extra volume probably formed no small draft on the slender resources of the Institute.

THE HUMMING TELEPHONE.

Accounts of the recent Conversazione of the Royal Society seem to show that the exhibits possessed more than usual interest. Every year the Royal Society holds a conversazione resembling somewhat the opening of the National Gallery of Art, in that the scientific exhibit of the year is made for the inspection of all beholders. The very successful A. I. E. E. Conversazione of 1901 showed that a similar custom could easily take root in New York, and we hope that the annual Institute dinner may occasionally in the future give way to a function of this kind. Among the exhibits at London was a curious application of the humming telephone. It is well known that if a telephone is placed in the circuit of the ordinary microphone transmitter, and held closely facing the same, the two will set up conversation in the form of a particular hum or musical note, the telephone diaphragm stimulating the transmitter to this note, and the transmitter reacting on the telephone. The apparatus referred to is described as consisting of a vibratory steel bar carrying a microphone. Vibrations started in the rod, generate currents of the same frequency in the microphone circuit. These currents are caused to act upon an electromagnet, which in turn stimulates the rod to yet more vigorous vibration. Induced alternating currents are tapped from the apparatus, considered as a high-frequency generator, for inductance measurements, or tests, in which only a relatively feeble unit-frequency current is desired.

THE ARCHITECTURE OF CENTRAL STATIONS.

As a rule central stations are designed strictly in accordance with the Socratic canon of beauty, and judged by the ideals of date later than B. C. they are generally masterpieces of ugliness. With a few exceptions they follow the graceful design of a shoe box surmounted by several lengths of stove pipe rampant. A paper has recently come into our hands read by Mr. C. S. Peach before the Royal Institute of British Architects, which throws a new light on the possibility of combining sound design with some degree of architectural grace. It is rich in illustrations, derived mainly from Continental practice, of power stations great and small, marked by an attention to artistic effect quite unknown in this country. We should not, of course, expect too much of a building designed for brutally utilitarian purposes, particularly in these days of twenty-story steel boxes, when he is accounted the best architect who can most scamp his design so as to secure the minimum cost per cubic foot of volume and square foot of floor space. And we realize, too, that there should be some degree of appropriateness to the desired ends—that Notre Dame with its towers converted into smokestacks would lack a certain unity of conception. But joking aside, Mr. Peach's admirable paper shows very plainly that it is possible to build great power stations on thoroughly sound engineering principles without sacrificing architectural dignity and beauty. It is a lesson worth studying for its own sake, however small be one's reasonable hopes that it may be generally taken to heart.

To begin with, one may divide power stations into three classes—steam-driven central stations, hydraulic stations and auxiliary or sub-stations in which steam power is either absent or quite inconsequential. The first class is obviously by far the most difficult to treat architecturally on account of the necessity of chimneys, which may be short or tall according as artificial or natural draft is used, but still are chimneys with their purpose fully in evidence. Add to this necessity the considerable space required for boiler and engine rooms, coal storage and other purposes and the difficulties of the situation are self-evident. Yet in spite of all this, Mr. Peach shows that it is possible to unite the severe requirements in buildings that are at once dignified and picturesque. Especially commendable are the power stations of the municipalities of Munich and of Vienna. The latter, with its four huge stacks and great size, was particularly difficult of treatment, yet the final result is most admirable. The Munich station, much smaller, is equally good and the chimney is of particular interest as an innovation upon the usual designs. And the most striking thing about these and some other fine Continental stations is that the excellent architectural result is obtained without any material increase of cost—merely by knowing how to obtain good effects by simple and inexpensive means. In this connection the author very shrewdly points out that a little additional expenditure on the building to the benefit of the surrounding property often brings large returns in good will and freedom from opposition and litigation. It is well to bear in mind that the rights of neighbors are being more and more upheld by the laws as time goes on, laying more and more emphasis on the doctrine that in a complexly organized community there are no absolute rights in property, but only predominant equities. It is this feature of the case that gives so great a value to public good will in enterprises of a permanent character.

Water power stations offer an entirely different set of conditions. Situated often in isolated situations and on sites closely defined by the hydraulic requirements, there is less need for an opportunity for architectural display. Yet now and then when a water power is developed in a city or when the situation is favorable elsewhere, capital effects can be and ought to be achieved. A beautiful example of the possibilities of hydraulic stations is cited by Mr. Peach in the station at Tivoli on the Tiber, which supplies the city of Rome. Here the aqueduct is built of masonry after the ancient Roman model and passes with hardly an architectural break into a stone power house clinging to the cliff above the river. More frequently, however, the necessity, real or supposed, of building very long and narrow stations makes anything by the crudest treatment quite impossible. The easiest case for the architect in electric power stations is found in the sub-stations now so frequently installed in connection with transmission plants and great central stations. These, generally speaking, are inside city limits, but they are not hampered by tall chimneys, and the apparatus brings no extraordinary requirements for space. The main difficulties are met with in securing adequate foundations so that no vibration shall be transmitted to neighboring buildings, and in planning the building so that the noise of the moving part of the machinery, if any, shall be suitably deadened. These are, so to speak, internal requirements on which engineer and architect must join forces; the exterior requirements give the latter for once a free hand. How effectively this opportunity may be grasped is admirably shown in Mr. Peach's own design for the great Mayfair motor-generator station of the Westminster Electric Supply Corporation, where a partially sunken station with graceful entrance porches is crowned by an Italian garden. Even without so radical a departure from ordinary methods there is no reason why a sub-station should not be built with an appropriate and decorative exterior. Mr. Peach has assuredly done a public service in showing how the material accompaniments of a great modern industry may be made harmonious and even artistic. We hope his lesson will not be forgotten in future construction.

THE STRUCTURE OF THE ATOM.

The present trend of scientific speculation and theoretical investigation is toward the interior of an atom of matter, or to examine into the nature of its works. Until the last few decades, chemical and physical theories of matter stopped at the atom. Every substance was supposed to be formed of molecules, and each molecule was an orderly arranged group of a definite number of atoms. Atoms might be spherical masses like very minute shot. All atoms of the same element were identically alike, and atoms of different elements were characteristically and eternally different. Chemistry desired no more than this working hypothesis. Physics needed no more. The kinetic theory of gases was thereby satisfied. But the progress of natural philosophy in general, and the development of spectrum analysis in particular, upset the crude simplicity of the atom, and demonstrated that each atom was probably at least as complicated inside as a solar system. The advantage gained by this intra-atomic complexity was that it enabled all kinds of atoms to be ideally constructed out of one and the same fundamental stuff, for which mother material the name "protyle" has been used. Different dynamic systems of moving particles of protyle thus formed the different kinds of the atoms of chemistry. Different aggregations of atoms formed molecules, and aggregations of molecules, or groups of molecules, formed the matter that our senses reveal to us. The advance in theory thus made promoted the atom from the minimum thinkable mass to a relatively large mass, although of absolutely very minute dimensions. It made the minimum thinkable quantity of mass the particle of protyle. The question then arose as to whether these ultimate particles of protyle were to be regarded as point-spheres, like shot, the shot in different atoms being all alike, but differing in number, grouping or activity. One form of the most recent electron theory regards these particles of protyle as point-charges of electricity. On this view different groupings of electric charges make up the different atoms, and so on. Consequently, on this theory, all matter is ultimately electricity, and electricity may be a special localized disturbance of the all-pervading ether; so that all matter is ultimately energized ether.

As bearing on this hypothesis, a very interesting paper "On the Structure of the Atom," by Prof. J. J. Thomson, appears in the *Philosophical Magazine* for March last. The article contains an analysis of the actions that would occur in an atom consisting of a number of electric point-charges subjected to certain assumed forces. The forces involved are three, namely: a centripetal electric force, toward the center of the atom, varying directly as the distance therefrom; secondly, a repulsion, due to the action of similar electric point-charges in the neighborhood; and, thirdly, centrifugal forces of inertia, due to planetary rotation of the charges about the center. This represents a sort of Newtonian planetary system inside the atom, except that the attraction toward the central sun increases as the planet is farther away, and that the planets push each other apart instead of mutually attracting. The writer tries to determine mathematically from these premises what groupings and velocities of the electrons, or corpuscle point-charges, would form stable atomic systems. The general problem in three dimensions has been too hard even for the well-known mathematical powers of the writer—but a number of solutions are given for two-dimensional distributions, in which the corpuscles are arranged in concentric rings, the rings moving around in the direction of their length, or tangentially to themselves.

It is shown in a masterly way that rings of three, four, five or six corpuscles are stable, at certain planetary velocities. Above six corpuscles, the rings require interior planets to effect stability. In the case of twenty-five or more corpuscles, three concentric rings would be required. With thirty-five or more, there would have to be four concentric rings, one within the other, and with fifty-five or more corpuscles, five concentric rings would be needed. The natural periods of vibration of such atomic systems would be both rotational and perturbational. The rotational period would be the period of a planetary "year," divided by the number of corpuscles in the ring belt. The perturbational periods would depend upon the proximity between neighboring corpuscles. It is shown that if all the possible stable arrangements are produced, the atomic systems may become periodic in their properties, suggesting the periodic series of the chemical elements as discovered by Mendelief. A number of other interesting chemical or electrochemical properties are indicated. While the theory of the article is necessarily tentative, yet it foreshadows the possibility of great progress being effected at no very distant date in theoretical and physical chemistry. It is quite conceivable that some day the student of chemistry will be able to compute mathematically all the possible chemical reactions of substances, without having to carry out the actual process in the laboratory. Howbeit, that end is not yet.

Honors at Stevens to Electrical Engineering.

The Stevens Institute of Technology, Hoboken, N. J., has contributed a large number of useful and influential men to all departments of engineering, and to-day has many worthy representatives in the field of mechanics and electricity. This year in the person of Mr. J. W. Lieb she has seen one of her graduates elected president of the American Institute of Electrical Engineers, a body on whose council she has already had recognition. And now a further bond of relationship is to be found in the fact that last week at the commencement exercises, Mr. Edward Weston was made by Stevens a Doctor of Science, this being the first time in its history that the Institute has conferred that degree. The relation between Mr. Weston and the graduates of Stevens has always been close and intimate, and ever since this distinguished engineer and inventor began his career at Newark, near by, the shops and plants under his management or name have given abundant occupation and opportunity to Stevens men. Not long ago Mr. Weston, an Englishman by birth, was made a Doctor of Laws by McGill University, but it is even more fitting that the specific technical recognition should come from New Jersey and the country of his adoption.

In presenting Mr. Weston for the degree of Doctor of Science on June 16, President Humphreys said: "In addition to conferring degrees for work done in course, Stevens Institute, in common with other higher institutions of learning, exercises the high privilege of conferring honorary degrees upon men who have, by work done outside as well as inside of college walls, proved their right to be acknowledged as men of eminent intellectual attainment. While it is a great privilege to be authorized to so seek out and honor those who have proved themselves worthy, it is a privilege not lightly to be exercised. That Stevens Institute has not misused its privileges in this connection is indicated by the fact that during the past thirty-two years we have graduated 1,089 men; but we have, during the same time, conferred only 15 honorary degrees. This year the faculty and trustees have decided to confer for the first time the honorary degree of Doctor of Science. I present for the honorary degree of Doctor of Science Edward Weston, Doctor of Laws of McGill University, Toronto, original investigator in science, inventor and engineer.

"This is frequently spoken of as the age of electricity, and this because during the past few decades the manifestations of electricity have been studied until it has been possible in many marvelous ways to apply for the use and benefit of mankind the laws of nature so discovered. In so discovering and applying the laws of electrical science, probably no one has done more for mankind than Edward Weston. Many years ago he made radical improvements in the art of depositing the various metals by electricity. He developed the dynamo machine to take the place of batteries in this work. He took the lead in the work of investigating the separate losses in dynamo machines and his inventions served to greatly reduce those losses. He developed dynamo machines for electric lighting and power transmission. He built the first factory in the United States for manufacturing dynamo machines and in this factory the electric current was first used for transmitting power. He invented processes, machines and devices for arc and incandescent lighting, including the copper-coated carbon, carbon filaments from amorphous cellulose, and the hydro-carbon treatment now universally used for flashing incandescent lamp filaments.

"In later years he discovered two alloys having a zero temperature coefficient, now universally used for resistance standards. He invented a standard cell with a practically zero temperature coefficient, and he invented and developed a most complete line of direct indicating electrical measuring instruments which to-day are the standards throughout the civilized world. It is seldom that the ability to carry on work in the line of scientific research is found combined with the ability to practically apply the laws so discovered as is found in the person of Mr. Weston. In acknowledgment of the varied, original, important and great amount of scientific work he has accomplished, the record of which I have barely outlined, I ask you to confer upon Edward Weston the degree of Doctor of Science."

Another interesting part of the exercises was the address to the graduating class by Mr. Walter C. Kerr, a trustee of Cornell University, and president of Westinghouse, Church, Kerr & Co., who with wonted felicity and suggestiveness spoke of the importance of "The Point of View." He called attention to the fact that the so-called liberal education had always been highly academic, while trade school engineering had been strictly non-academic. But the two had joined hands in the engineering institutes, with advantage; but there was a danger of engineering education now becoming too academic, a tendency to be watched. He asserted that the highest refinement of knowledge follows from the highest use of the senses. "It is only within the past century that the human mind has seemed capable of turning from the lesser resistance of intellectual attainment to the greater capacity for physical comprehension and observation. We have but recently come to the era of intense mental operations, dealing with laws and principles which require insight greater than the intellect can grasp unless aided by the senses." He expressed the hope that the spirit of engineering as found in practice would form a more definite part of engineering education, and suggested the idea that professors would eventually come to a system of devoting all their time to teaching while they taught, but would go periodically into the world, a few years at a time, for practice.

Mr. Kerr then speaking more directly to the students, urged on them the importance of the right "point of view" as they began active life and went through it. Adam, William Tell and Sir Isaac Newton each had an affair with an apple, but with different results. They were to neglect no opportunity as too small, and were to remember that knowledge after all had not much to do with effectiveness. It was a good tool, but not the performing vital form. They must cultivate singleness of purpose. The power of concentration, however, is not in the books. From directness of purpose follows diligence in getting what one is after, and in getting it all. The mediocrity of compromise was to be avoided. To be right they must be 100 per cent. right. Much of our engineering is only done once, and it must be done right that once. Real power is ability to perform right the first time that which a man never did before. Hence, by sequence, clearness of thought is also essential, aided by the moderate cultivation of system, without slavery to which each can find his own logical way. Intuitions were thus quick reasonings, but all ideas little or big were only valuable when put into execution. A point of view is involved in the power to rationalize, which is in itself a great check upon error.

Mr. Kerr enlarged quite interestingly also upon the "point of view" in engineering expression—designs, drawings, mathematical determinations, words, work done, of which words were the lamest. Hence, he urged learning the right use of words, for engineering documents were usually full of misstatements due to the careless use of language, so that plain, concise terms could not be overestimated. Facility was to be cultivated in reading the words of others. Per contra, one of the worst attributes, fundamentally born of conceit, was the tendency to fasten error and censure on others. A man needed to stand up in front of himself and ask, "What is the matter with me?" To admit an error or frailty of judgment is a measure of strength rather than weakness. Mr. Kerr then lay special stress on a cheerful disposition, pleasantry and non-contentiousness, because a reasonable optimism—to vote aye and believe that things can be done—is helpful to others and to enterprises.

Some of them probably had a special "point of view" in a preconceived notion of following some line of engineering. He warned them to be careful about their self-analysis. The field of engineering is large and has room for all, whether constructive, inventive or contemplative. Some tended toward professional, others toward trade work. He could not help, for himself, a certain predilection in favor of a young man being just an engineer—not specializing too young, but developing along versatile lines, ready to turn his hand equally well to any task within his general scope. The man who believes he can apply himself in one direction about as well as another, will come nearer doing it than one who thinks he cannot. They would also doubtless try to improve things when they started. It is a legitimate purpose if not overworked. The one improvement that most things needed was in the line of sufficiency. A "point of view" rarely considered had to do with environment and the power to vary. All the way up from protoplasm, environment grew constantly more intricate and resistance retarded evolution. This complexity presses down and holds back. Environment was not a producer, but often against production, so that all the good they did must come out of themselves. It was the inherent capacity to perform with their own brain that would make them whatever they became and not the mere transmission of what they had acquired. Many a man who had received an education has not got any, because it never became part of his personality and slipped away. Many a man had gone through experience without acquiring it.

Bear River Power Plant and Utah Transmission Systems—II.

(Concluded.)

FROM the power house the three-wire transmission line passes up the east bank of the river and skirts the base of the Wasatch Mountains, keeping for the most part above the cultivated farms. It taps into the Utah Light & Railway Company's line at Ogden. The total transmission distance from the power house to Salt Lake City is 82 miles and the route of the line is shown on the map, Fig. 17, to which reference will be made later.

The transmission line consists of three No. 0 soft-drawn copper wires, carried on 40-ft. round cedar poles set 120 ft. apart. The insulators are carried on two cross arms, as shown in Fig. 12. The lower arm, which carries two wires, is 7 ft. long and is bolted to the pole 5 ft. below the top. Additional support to the arm is provided by two 30-in. x 1¼-in. x ⅜-in. iron braces, fastened with lag

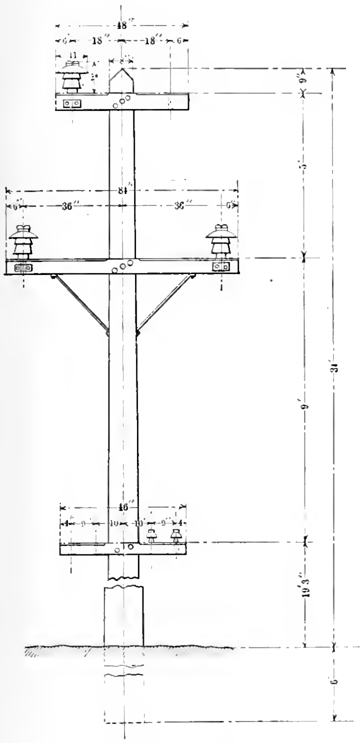

FIG. 12.—ELEVATION OF 40-FT. POLES.

screws. The top insulator, instead of being mounted on the top of the pole, as is frequently done in the West, is carried by a 4-ft. cross arm bolted to the pole 9 in. below the top, thus giving a better mechanical construction. Both cross arms are 3¾ in. x 5¾ in. in cross-section. The top insulator is mounted 18 in. from the center of the pole and on successive poles is reversed from one end of the arm to the other, as may be seen in Fig. 12. This arrangement is an advantageous one in case of a broken insulator, as the wire will fall on the cross arm and against the pole and thus be kept from causing a short-circuit by falling on the wires below. The three wires, of course, are not spaced to form an exact equilateral triangle, but it is an approximate one, with 6-ft. sides.

In the construction of the pole line the insulators have been relied upon entirely for insulation and the rest of the line has been made as strong mechanically as possible. The insulators are of the Locke brown porcelain type, made in three pieces and afterward cemented together. Each insulator was tested at the factory with a 120,000-volt current before being accepted. The insulators are 10 in. high, 11 in. in diameter and weigh sixteen pounds apiece. They are mounted on cast-iron pins, which have a height of 10 in. above the cross arm and are threaded at the top to receive the insulator. The cast-iron

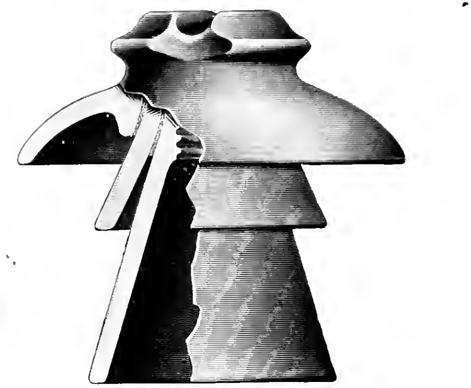

FIG. 13.—PORCELAIN INSULATOR.

shank of the pin is 1¼ in. in diameter and 5 in. long, and has a ⅝-in. round steel core, which projects below and is threaded to receive a nut for bolting the pin securely to the cross arm. Further security is provided by 3 x 4 x ⅛-in. plates bolted to the sides of the cross arms opposite the pins.

Fig. 13 shows the insulator used. The middle and lower shells were cemented together at the factory, and the top shell cemented on in the field. Fig. 14 shows an insulator under test at 75,000 volts with

FIG. 14.—INSULATOR UNDER TEST AT 75,000 VOLTS.

a shower of water corresponding to a precipitation of ¾ in. per minute, the test covering 15 minutes. The standard test under normal conditions is at 100,000 volts.

Nine feet below the large cross arm is a 46-in. cross arm which carries a No. 9 iron-wire telephone circuit. The telephone line is transposed every half mile and is said to give perfectly quiet service, although there is an induced voltage between either side and ground sufficient to light an incandescent lamp. For the use and convenience of the men patrolling the line, telephones are connected at intervals along the route as well as at the power house and receiving station in Ogden. They are placed in booths so insulated as to protect the user from danger of an accidental cross between high-tension and telephone wires in case of a breakdown.

The entire output of the Bear River plant of nearly 3,000 hp is sold by the Utah Sugar Company to the Utah Light & Railway Company, as already mentioned, and the latter company operates the station and transmission system. It has recently been decided to install a third unit at the power house of the same size and style as those now in operation.

The concrete work and power house were built under the direct superintendence of Mr. J. C. Wheelon, superintendent of the Utah Sugar Company's canal system. The entire plant and transmission system was designed and supervised by Hayward & Gray, consulting engineers of Salt Lake City. To Mr. O. H Gray, successor to the firm of Hayward & Gray, appreciation is due for kindly supplying data and illustrations for this article.

NOTES ON UTAH TRANSMISSION LINES AND SALT LAKE STATIONS.

A general idea of the extensive interconnected power transmission

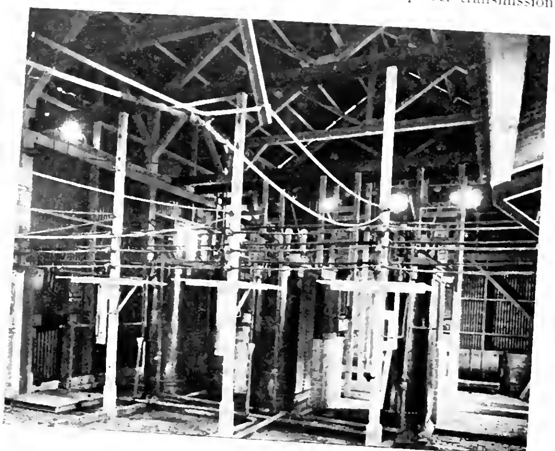

FIG. 15.—INTERIOR OF SUB-STATION, SHOWING HIGH-TENSION BUS-BARS, TRANSFORMERS, ETC.

system in Utah may be obtained from the map, Fig. 17. This map shows the lines of the Utah Light & Railway Company, including the Bear River system, indicated by a heavy, full line, the circuits of the Telluride Power Transmission Company indicated in heavy broken lines and the system of the American Fork Canyon plant in crossed lines.

The Utah Light & Railway Company operates the Bear River, Ogden and two Cottonwood water power plants and three steam stations in Salt Lake City. The Telluride company has a water power

FIG. 16.—INTERIOR OF SUB-STATION, SHOWING LIGHTNING ARRESTERS, ETC.

plant at Logan, 85 miles north of Salt Lake City, and another at Provo, 45 miles south. These two stations are connected by a duplicate pole line and at Salt Lake taps are taken off to a transmission sub-station of the Utah company situated close to a new station of the company in the western part of the city. At this station the power from the Telluride system and the company's northern lines

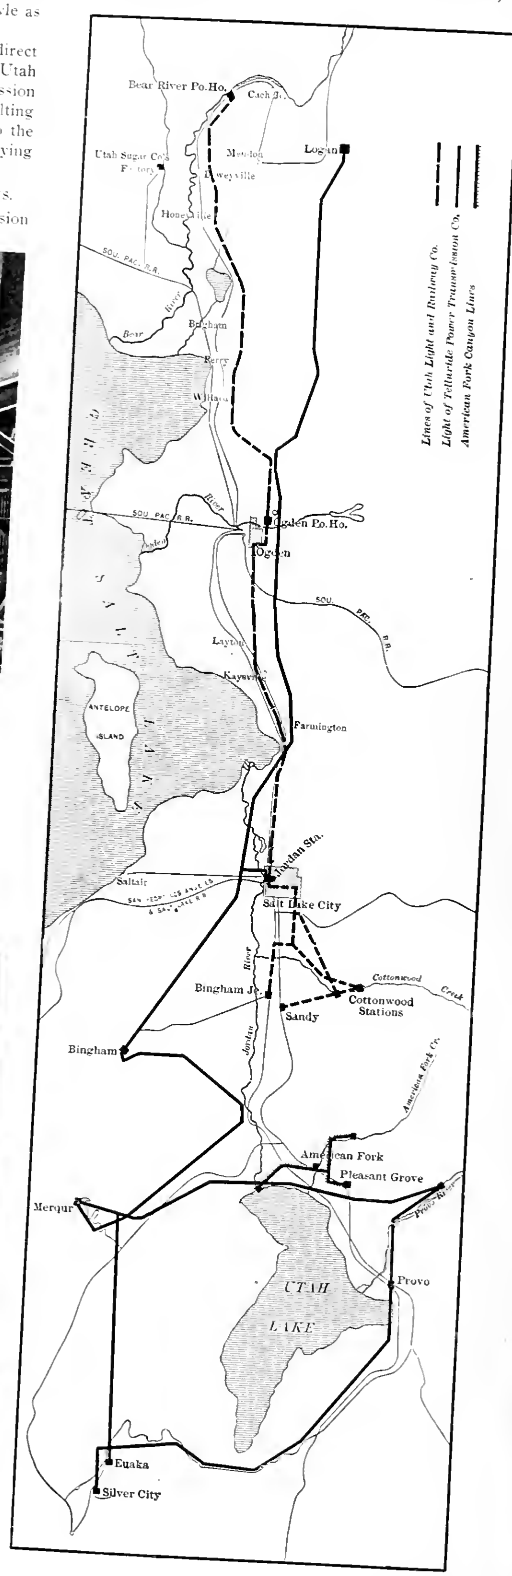

FIG. 17.—MAP OF TRANSMISSION SYSTEMS.

is received and stepped down from 40,000 to 2,300 volts by means of water-cooled, oil-insulated transformers. This sub-station now has a capacity of 2,700 kw, but it is being rebuilt and enlarged and by fall will have a capacity of 6,000 kw and will receive the power from all the transmission lines of the company, including those from the Cottonwood stations, which now come into another sub-station at a lower voltage. The sub-station is equipped with lightning arresters, static interrupters, air-break switches and a complete set of indicating and recording instruments.

The steam station is called the Jordan station, as it is located on the bank of the Jordan River. It was erected as a temporary power house to carry the company through its peak loads until a large steam turbine central station now planned by the company can be erected. The equipment consists of six 250-hp Babcock & Wilcox boilers set in three batteries, and a 1,200-hp Hamilton Corliss engine, which drives by means of a large belt a 750-kw alternator. This plant is used for a few hours each night to help over the peak of the load.

It is interesting to note that these six water power and three steam stations are all operated in parallel through the low-tension side, and although some of the stations are nearly 150 miles apart the generators operate in perfect synchronism.

Fig. 18 is interesting as showing how a high-tension transmission line from the Cottonwood plants is brought through Fourth South

FIG. 18.—HIGH-TENSION LINE, SALT LAKE CITY.

Street, one of the principal streets of Salt Lake City, on 60-ft. poles. These poles are set in the center of the street, as are practically all poles in the city on account of the unusual width of the streets.

An interesting transmission system in Utah is that from American Fork Canyon to Utah Lake and indicated on the map by crossed lines. This system is a striking illustration of the use of water power as an aid to irrigation. The power in this case is transmitted electrically to the head of Utah Lake, where it is used to drive four 100-hp pumps, which raise about 500 cu. ft. of water per second out of the lake into a system of five large canals. These canals irrigate the Salt Lake Valley. Power for the pumps was formerly supplied by the Jordan Narrows plant, but the American Fork plant has recently been enlarged and the transformers at the pumping plant have been rearranged for this purpose. The reconstruction work was done by Mr. Owen H. Gray.

Deep Sea Cable Between Valdez and Nome.

The second consignment of deep sea cable now being laid by the Government between Valdez and Nome has just been shipped in a special train of thirty-one cars over the Lackawanna Railroad. This shipment consists of 800 tons, and is part of an order for thirteen hundred miles of submarine cable being executed by the Safety Insulated Wire & Cable Company.

An Object Lesson to the Public in Metering.

An interesting piece of apparatus for the instruction of the general public in regard to electric light meters is in operation at the main office of the Denver Gas & Electric Company, on Seventeenth Street, Denver, Colo. The device consists of eight incandescent lamps mounted in porcelain sockets on a wooden panel about 25 in. square; an electric meter and eight snap switches. The lamps are wired to the regular 100-volt alternating circuit of the company and are numbered consecutively from one to eight. The first and eighth lamps are 4 cp each, while the candle-power of the intermediate lamps is 8, 10, 16, 25, 32 and 50 in the order named. Each one or any number of these lamps may be switched into circuit at the will of any customer desiring to experiment with the meter. The snap switches are numbered consecutively to correspond with the different lamps and are mounted in a horizontal row at the bottom of the board. A great number of candle-power combinations are thus possible for experimental purposes, and these vary from 4 to 149 cp. Even the effect of one candle-power may be noted by combining the lamps properly.

The meter is a 100-volt, 10-amp. watt-hour instrument mounted in a glass case, and designed for 60-cycle current. It is direct reading and has a dial capacity of 100,000,000 watt-hours. The brake disc is marked at a point on the circumference so that the revolutions may be accurately tuned and counted. In the center of the panel is a notice to the public as follows:

"THIS IS AN ELECTRIC METER"

like those which are in the houses and stores of our customers, except that this one is constructed partly of glass in order that you may see how an electric meter is made and how it operates. This particular meter measures the current that supplies the lamps on the board surrounding it. By turning on one lamp at a time or by turning on lamps of different candle-powers you can see that the motion of the moving parts of the meter varies in proportion.

"An electric meter is an almost perfect measuring instrument. It measures current with great accuracy. We test all our consumers' meters at frequent intervals to see that they are registering correctly, and then abide strictly by their readings in making out our consumers' bills.

"We have no control over the size of our consumers' electric bills. That is a matter which rests entirely with the consumers themselves. We cannot make their bills larger or smaller unless we should go into their houses and turn on or off some of their lamps. If the consumer thinks his bill is too large we are glad to do all we can toward helping him ascertain the facts in the case. If he thinks his meter is incorrect we shall be glad to take his meter out and test it in his presence. If the test shows that the meter has been registering against him we will rebate him accordingly.

"We are especially desirous that our customers should learn to read their own meters so that they may verify the correctness of our bills and keep tab on their consumption of current from time to time during the month. The reading of an electric meter is as easy as telling the time of day by a clock. You simply begin with the left-hand dial and set down in turn the smaller of the two figures between which the "hand" on each of the dials appears and then add two ciphers. This will give you the reading in watt-hours, and, pointing off three places from the right gives it in "kilowatt-hours." Subtracting the previous reading from this one will show how much current has been consumed since the previous reading. Please ask us for a copy of our printed instructions for reading meters.

DENVER GAS AND ELECTRIC COMPANY."

At the right of the lamp panel is a gas meter connected to six different sized burners, a similar notice being posted upon the board over the meter, designed for the reading of gas consumers.

The printed instructions for reading electric meters consist of a sheet of cardboard about 5 by 7 in. upon which are inscribed regular meter dials with movable hands, so that various readings may be set up at will. Full directions follow the printed dials, and the card is fitted with eyelets and a hook, so that it may be used as a bill file.

By means of this object lesson the Denver Company meets its consumers frankly and squarely upon the hitherto vexing meter problem.

Foucault Pendulum Systems.

By Ernest K. Adams.

In a preceding issue of this journal* a number of electrical systems have been illustrated and described, whereby the vibrations of a Foucault pendulum may be prolonged. These systems are based upon the electrodynamic action of two coils of different diameters, the smaller of which is incorporated in the bob of the pendulum and the larger mounted symmetrically beneath the said pendulum. By simultaneously sending currents through these coils in the same or opposite directions, the pendulum coil may be accelerated respectively toward or away from the center of the large coil. The methods of controlling the accelerating current may be manual or automatic. From a test made with a 16-ft. pendulum, the results obtained would indicate that the principles of the systems are correct. The burden of the paper was to suggest a line of investigation in this subject to those who have the facilities for swinging pendulums whose lengths may run up to that of the original one in the Pantheon at Paris. In a recent communication to the Electrical World and Engineer, Mr. S. Tideman suggests that the pendulum may be accelerated by raising and lowering the suspension of the system when the bob of the same is traveling respectively away from and toward a vertical line passing through the point of suspension. While it is known that the suspension of a Foucault pendulum is the most sensitive portion of the organization, it may be possible to so accelerate it there that the component of the earth's rotation will not be seriously influenced in its action upon the pendulum. In the present paper the writer begs to suggest several designs for carrying out this idea. The first is a mechanical one, which is adapted to pendulums of moderate length, such as would be employed in general physical laboratory work, while the others are electrical in character and suitable for pendulum systems of considerable height, as would obtain in the Pantheon or other demonstrations. In all cases the movement of raising and lowering the suspension is caused to imperceptibly start and stop, the maximum rate of vertical motion occurring at the center of the predetermined displacement.

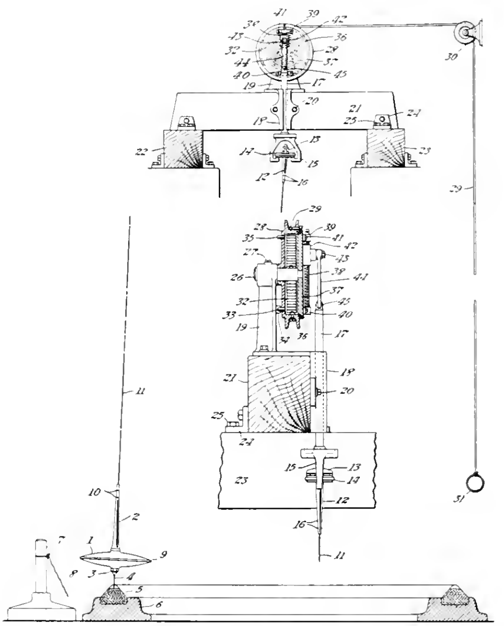

FIG. 1.—MECHANICAL SUSPENSION TYPE OF FOUCAULT PENDULUM.

MECHANICAL SUSPENSION TYPE.

The suspension of the pendulum is designed to be given its reciprocating travel by means of a drum, link and plunger combination, which is operated by drawing a cord when the pendulum is moving toward the center of its amplitude and slowly releasing the aforesaid cord during the outward passage of the pendulum. The cord may extend from the suspension mechanism down to the operator upon the floor below, irrespective of the length of the pendulum. The length of stroke of the suspension may be adjusted to suit any pendulum of moderate length, thereby adapting a given size of the apparatus to a majority of cases.

A diagrammatic view of the arrangement is shown in Fig. 1.

The pendulum consists of a disc-shaped bob, 1, having a post, 2, secured therein by a hexagonal nut, 3. Threaded into the lower extremity of the post, 2, is a fine needle, 4, which is adapted to make furrows through the top of a pointed heap of sand, 5, placed in a wooden ring, 6. This ring, 6, is mounted symmetrically beneath the pendulum system. The top of the ring, 6, is provided with angular graduations. A weighted standard, 7, is furnished for maintaining the bob, 1, at one side, preparatory to setting the pendulum in vibration by burning a thread, 8, in the customary manner. A small depression, 9, is turned in the periphery of the bob, 1, for enabling the thread, 8, to be conveniently tied around the said bob, 1. Held by a number of screws, 10, in the post, 2, is a steel wire, 11, which extends upward to a knife-edge suspension made up of a post, 12, knife-edged member, 13, rocking ring, 14, and knife-edged supporting member, 15. The wire, 11, is secured in the post, 12, by several screws, 16. The supporting member, 15, is threaded upon the lower extremity of a rectangular plunger, 17, which is adapted to move in an accurately planed guide, 18. For preventing oil from the guide, 18, from running down the wire, 11, a groove is turned in the top of the supporting member, 15.

The guide, 18, forms a part of a journal casting, 19, which, together with the aforesaid guide, 18, is rigidly secured by several bolts, 20, to a wooden beam, 21. This beam, 21, rests upon two wooden supports, 22 and 23, the three members being secured together by a number of angle irons, 24, and bolts, 25. Journaled upon a shaft, 26, which is held in the casting, 19, by a set screw, 27, is a drum, 28, around the periphery of which is wound a cord, 29. This cord, 29, is secured to the drum, 28, by tying a knot in it, and passes over a pulley, 30, which is fastened to any convenient support. The cord, 29, is terminated by a ring, 31, at any desired height from the floor. A helical spring, 32, is secured to both the shaft, 26, and the interior of the drum, 28. This spring, 32, normally maintains a pin, 33, let into the face of the drum, 28, against a rubber-covered stop, 34, mounted upon the casting, 19. For limiting the angular motion of the drum, 28, to one-half a turn, a second pin, 35, is let into the side of the aforesaid drum, 28. Secured by several screws, 36, to the front of the drum, 26, is a disc, 37, upon which a threaded shaft, 38, is journaled by two bearings, 39 and 40. A number of screws, 41, serve to hold the bearings, 39 and 40, in place. Mounted upon the threaded shaft, 38, is a member, 42, having secured thereto a bolt, 43, which journals a link, 44. The lower end of the link, 44, is journaled in the top of the plunger, 17, by a pin, 45.

Presupposing that the apparatus has been set up, the bob, 1, tied by the thread, 8, in the plane of the meridian, and the threaded shaft, 38, adjusted until the right eccentricity of the bolt, 43, is obtained for accelerating the pendulum system, the thread, 8, is burned and the pendulum thereby set in vibration. With each oscillation of the pendulum the needle, 4, will make an indentation in the sand, 5, and the angular change of the plane of vibration of the system will be thereby recorded. When the amplitude of the oscillations of the pendulum are noticed to be decreasing below that desired, the cord, 29, may be drawn down and the drum, 28, revolved through one-half a revolution while the bob, 1, is traveling inward. On account of the construction of the apparatus, the suspension during this motion of the drum, 28, will be caused to move downward through the predetermined displacement, beginning and ending its motion slowly and attaining a maximum rate in the center of its stroke. This action will give the pendulum an acceleration. Upon the bob, 1, now traveling outward, the cord, 29, may be slowly released, the drum, 28, being turned by the helical spring, 32, in the opposite direction to that just previously occurring, thereby lifting the suspension and giving the pendulum another acceleration.

This cycle of operations may be repeated until the amplitude of the vibrating system has been restored to that desired. After several trials the motion of the cord, 29, may be readily kept in step with the oscillations of the pendulum. By following the path of the needle, 4, over the graduations on the top of the ring, 6, or

*See Electrical World and Engineer, January 30, 1904, p. 211.

comparing the indentations made by the needle, 4, in the sand, 5, with the aforesaid graduations, the number of degrees angular variation of the pendulum's plane may be noted. If the pendulum should be mounted at either of the poles of the earth, the plane of oscillation would appear to make one complete turn in 24 sidereal hours. At the equator there should be no relative motion between the pendulum's plane and the earth. For intermediate points between the poles and the equator, the rate of revolution is proportional to the sine of the latitude of installation, the angle turned through in one hour being equal to 15 degrees multiplied by the sine of the latitude. The rotation of the plane is clockwise and anti-clockwise from above for northern and southern latitudes, respectively. For the latitude of New Haven, Conn., the hourly variation of the plane should be 9.903 degrees, or one complete revolution in 36.35 hours. In New York City the angular change should be 9.801 degrees per hour or one turn in 36.73 hours. It is hardly to be expected that these values can be exactly obtained experimentally. The best results will be obtained when the pendulum wire is of considerable length, the suspension rigidly mounted and the influence of air currents eliminated.

ELECTRICAL SUSPENSION TYPES.

The present Foucault pendulum systems are intended to be electrically operated, the methods of control being either manual or automatic. The reciprocating rectilinear movement of the pendulum's suspension is produced from circular motion by the same device as shown in Fig. 1. An electric motor is provided for continuously driving this mechanism in synchronism with the vibrations of the pendulum. A clockwork drive may be employed for this purpose, but on account of the necessity of having to frequently wind it up, it is believed preferable, particularly in a large pendulum system, to provide a continuously revolving motor. The motor is run at a fairly constant speed, and is allowed to operate the suspension whenever a releasing magnet is energized. The circuit of this releasing magnet is designed to be either manually or automatically closed in several ways by the pendulum at certain points of its amplitude. The first method shown consists in allowing the pendulum's needle and a stationary metal ring to form the terminals of the secondary circuit of a high-potential transformer. The primary of the transformer includes the releasing magnet and a suitable source of alternating current. When the pendulum is at the end of its swing, a series of sparks are allowed to pass through the small air-gap between the pendulum's needle and the metal ring, thereby temporarily closing the secondary circuit, increasing the current in the primary and operating the releasing magnet. By this method of control there need be no material contact with the pendulum system. In the second design the circuit of the releasing magnet is periodically closed by employing some electrically conductive substance such as graphite for the pendulum's needle to record the angular change of the plane of oscillation in. The employment of graphite thereby serves a double purpose. In the third illustrated method of control, the circuit of the releasing magnet is closed at intervals by a mercury contact.

By referring to the drawings, Fig. 2 is a diagrammatic scheme of the electrical pendulum system, Fig. 3 a wiring diagram of the modified method of controlling the automatic accelerating action by providing a conductive substance for the pendulum's needle to pass through, and Fig. 4 a detail of the mercury contact for the same purpose.

The construction consists of a pendulum wire, 46, which is fastened by several screws, 47, to a post, 48. This post, 48, passes through a disc-shaped iron bob, 49, and is secured therein by a hexagonal nut, 50. A fine needle, 51, is threaded into the lower end of the post, 48. The upper extremity of the pendulum wire, 46, terminates in a knife-edge suspension, which is made up of a central post, 52, knife-edged portion, 53, rocking ring, 54, and supporting knife-edged member, 55. The wire, 46, is secured in the post, 52, by several screws, 56. The supporting member, 55, is threaded upon the lower extremity of a plunger, 57, which is guided in a tube, 58. The tube, 58, passes through a wooden beam, 59, and a journal casting, 60, the said tube, 58, being held in place by a hexagonal nut, 61, and the casting, 60, secured by several bolts, 62. The plunger, 57, is prevented from turning by a pin, 63, which extends through the tube, 58, and a slot, 64, milled in the aforesaid plunger, 57. The beam, 59, rests upon two wooden supports, 65 and 66, the three members being fastened together by several angle irons, 67, and bolts, 68. The supports, 65 and 66, in turn are fastened in place by a number of angle irons, 69, and bolts, 70. A casting, 71, is pinned to a shaft, 72, which is journaled in the main casting, 60. Mounted in two extensions from the casting, 71, and secured therein by a bushing, 73, is a threaded shaft, 74. The upper extremity of the shaft, 74, is provided with several holes, 75, for enabling a close adjustment to be made. Mounted upon the shaft, 74, is a member, 76, having threaded therein a bolt, 77, which serves to journal a link, 78. The lower extremity of the link, 78, is journaled by a pin, 79, in the upper end of the plunger, 57. A mechanical combination is situated adjacent to the suspension for revolving the shaft, 72, with each vibration of the pendulum.

This arrangement consists of a journal casting, 80, which is fastened by several bolts, 81, to a wooden block, 82, in turn secured in place by several angle irons, 83, and bolts, 84. Journaled in the

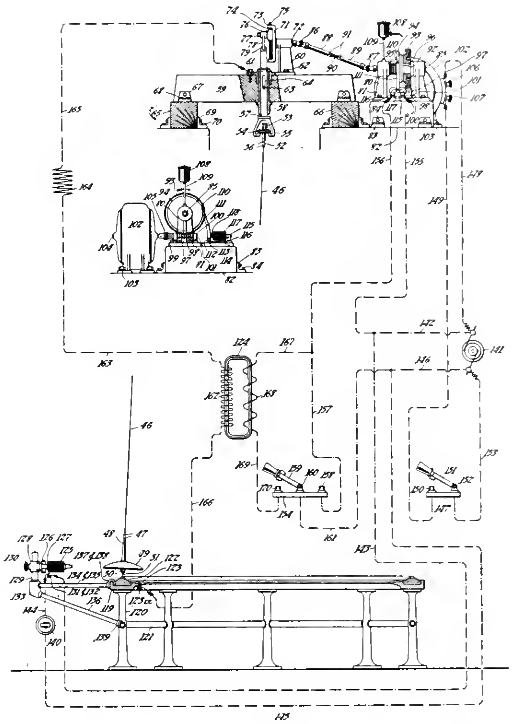

FIG. 2.—ELECTRICAL SUSPENSION TYPE OF FOUCAULT PENDULUM.

casting, 80, is a shaft, 85, which is mechanically connected with, but insulated from, the other shaft, 72, through the medium of two universal couplings, 86 and 87, tubes, 88 and 89, fibre joints, 90, and pins, 91. Secured upon the shaft, 85, by a key, 92, is a worm gear, 93. The left-hand side of the worm gear, 93, is adapted to form a friction clutch in connection with a disc-shaped member, 94, which is both journaled upon the shaft, 85, and maintained against the worm gear, 93, by a compression spring, 95, situated between the aforesaid disc, 94, and the journal casting, 80. A roller thrust bearing, 96, is placed between the worm gear, 93, and the journal casting, 80. A worm, 97, mounted upon a shaft 98, which is journaled in two bearings, 99 and 100, secured to the main casting, 80, by a number of screws, 101, meshes with the worm gear, 93. An alternating-current motor, 102, is secured by a number of bolts, 103, adjacent to the wooden block, 82, and the shaft, 104, of the aforesaid motor, 102, is connected with the worm shaft, 98, by means of a pin and slot coupling, 105. The terminals of the motor, 102, are numbered 106 and 107. An oil reservoir, 108, is mounted upon the journal casting, 80, by a standard, 109, the purpose of which reservoir, 108, being to lubricate the friction clutch.

Formed upon the periphery of the disc, 94, is a tooth, 110, which, by the rotation of the worm gear, 93, is maintained against the extremity of a lever, 111, journal in a casting, 112, secured to the main casting, 80, by several screws, 113. The top of the lever, 111, is maintained against the circumference of the disc, 94, by a retractile spring, 114, the right-hand end of which is fastened to a support, 115. The support, 115, which is secured to the main casting, 80, by two screws, 116, serves to mount an electromagnet, 117. An armature, 118, is secured to the lever, 111, adjacent to the poles of the electromagnet, 117. It will be understood that when the electric motor, 102, is running, the disc, 94, will be normally prevented from revolving, the worm gear, 93, rotating independently of the aforesaid disc, 94. When, however, the electromagnet, 117, should be temporarily energized, the upper extremity of the lever will be moved away from the tooth, 110, and, by reason of the friction drive, the disc, 94, will be allowed one complete revolution. With this movement the suspension will be lowered and raised in its accelerating function. The amount of work consumed at the friction clutch when the worm gear, 93, is revolving and the disc, 94, stationary, should be more than the work required to turn the suspension shaft, 72. The power of the motor, 102, should be considerably more than that required to overcome the friction between the worm gear, 93, and disc, 94, in order that there will be no appreciable variation in the speed of the aforesaid motor, 102, when the disc, 94, is revolving or stationary. The speed of the motor, 102, is also so chosen and the worm gearing so proportioned that in the normal running of the aforesaid motor, 102, the disc, 94, will make, when magnetically released, one complete turn in approximately three-quarters or seven-eighths of the time of one oscillation of the pendulum.

Situated symmetrically beneath the pendulum system upon the floor is a wooden ring, 119, which is made in sections and supported by a series of iron posts, 120, and tubes, 121. The wooden ring, 119, is provided with a groove in which sand, 122, is placed. Secured to the inner surface of the ring, 119, is a metal annulus, 123, which is made in sections, and forms one of the terminals of the secondary circuit of a high-potential transformer, 124. The pendulum's needle, 51, performs the function of the other terminal of the secondary circuit of the transformer, 124. A binding post, 123A, is secured to the metal ring, 123. The outer surface of the ring, 119, is provided with angular graduations. A magnetic device is furnished for starting the pendulum in vibration. This arrangement consists of an electromagnet, 125, which is lightly journaled by two pointed screws, 126 and 127, in a casting, 128, maintained in any desired vertical position upon a standard, 129, by a knurled headed screw, 130. The terminals of the magnet, 125, are fastened to two binding posts, 131 and 132, which are mounted upon one end of the aforesaid magnet, 125. The standard, 129, is threaded into a casting, 133 in which three tubes, 134, 135 and 136, are secured. The tubes, 134 and 135, are terminated by two hook-shaped castings, 137 and 138, respectively, which are adapted to engage the circumference of the ring, 119. The lower end of the tube, 136, is provided with a casting, 139, which is so shaped as to rest upon one of the tubes, 121. It will be evident that the bracket thus formed may be moved to any desired position around the wooden ring, 119.

The operation of starting the pendulum system in vibration, presupposing that the apparatus has been carefully set up and the threaded suspension shaft, 74, adjusted to the correct position for accelerating the pendulum, consists firstly in moving the starting magnet, 125, around until the center of the ring, 119, and the said magnet, 125, are in the plane of the meridian. The pendulum bob, 49, is now brought up to the poles of the magnet, 125, and the said magnet, 125, energized by closing a switch, 140, which allows electricity to flow from a source, 141, of alternating current through a circuit made up of two wires, 142 and 143, binding post, 131, magnet, 125, binding post, 132, conductor, 144, switch, 140, together with the wires, 145 and 146. The sand, 122, in the ring, 119, is now pointed with a piece of cardboard. When desired the switch, 140, is opened, and the magnet, 125, now being without magnetism, the bob, 49, will be released and the pendulum set in vibration. The needle, 51, will now begin to chisel small furrows through the sand, 122. The induction motor, 102, is next started by closing a switch, 147, which completes a circuit made up of the source, 141, wire, 148, binding post, 106, motor, 102, binding post, 107, conductor, 149, clip, 150, switch blade, 151, journal post, 152, and wire, 153. When the motor, 102, has attained its normal speed the manual or automatic acceleration of the pendulum system may begin.

The manual acceleration is accomplished by closing over to the right-hand side for an instant a switch marked 154, when the pendulum bob, 49, is at the end of its amplitude. This action allows current from the source, 141, to flow through a circuit consisting of the wires, 142 and 155, releasing magnet, 117, conductors, 156 and 157, clip, 158, switch blade, 159, journal post, 160, together with the wires, 161 and 146. The magnet, 117, now attracts the armature lever, 111, which moves out of the path of the tooth, 110, thereby allowing the worm gear, 93, to revolve the disc, 94, for one turn, and giving the suspension of the pendulum a gentle downward motion while the bob, 49, is traveling inward and a corresponding upward displacement during the outward passage of the aforesaid bob, 49. On account of the speed of the motor, 102, being chosen such that the disc, 94, requires approximately seven-eighths of the time of one beat of the pendulum, the vertical motion of the suspension will cease when the bob, 49, is just about at the end of its outward swing. This will give sufficient time to again temporarily close the switch, 154, before the bob, 49, begins its return motion, at which time the same accelerating cycle will be repeated. The pendulum system can be constantly accelerated in this manner or periodically depending upon the adjustment of the threaded shaft, 74. As in the mechanical form of apparatus already described, the beginning and ending of the vertical stroke of the suspension plunger, 57, is gradual, the maximum rate of travel taking place at the middle of the stroke. This method of acceleration should not disturb the normal action of the vibrating system.

For the automatic operation of the pendulum, the threaded shaft, 74, should be so regulated that, when the system is constantly accelerated the bob, 49, will terminate its travel a short distance outside of the circular bank of sand, 122. Presupposing that the pendulum system has been set in motion in the plane of the meridian by the starting magnet, 125, the motor, 102, is running, and the amplitude of the pendulum has been allowed to decrease until the needle, 51, stops just outside the sand, 122, the blade, 159, of the switch, 154, is closed over to the left-hand side when the bob, 49, is in the middle of its swing. Upon the needle, 51, slowly passing over the metal ring, 123, as the pendulum is about to terminate its outward swing, the secondary of the transformer, 124, will be closed and a succession of sparks will pass through the small air-gap between the needle, 51, and ring, 123, the circuit consisting of the transformer secondary winding, 162, wire, 163, non-inductive resistance, 164, conductor, 165, suspension apparatus, pendulum wire, 46, post, 48, needle, 51, ring, 123, binding post, 123A, and conductor, 166.

This closing of the secondary has increased the current in the primary circuit, which is made up, from the source, 141, of the wires, 142 and 155, releasing magnet, 117, conductors, 156 and 167, primary transformer winding, 168, wire, 160, clip, 170, switch blade, 159, journal post, 160, together with the conductors, 161 and 146. With the increase of current in the primary circuit, the magnet, 117, has been energized and the disc, 94, allowed to slowly rotate, thereby giving the pendulum an acceleration during the ensuing return oscillation, the speed of the motor, 102, being so regulated that the turning of the disc, 94, will stop when the bob, 49, is within a short distance of the metal ring, 123. It will be noted that when the bob, 49, started its return motion the needle, 51, again passed over the metal ring, 123. This action caused the releasing magnet, 117, to be again energized and the lever, 111, moved away from the periphery of the disc, 94, thereby producing no result or insuring the starting of the aforesaid disc, 94, if for any reason it failed with the outward swing of the pendulum just previously occurring. When the needle, 51, against reaches the other side of the ring, 123, the same accelerating cycle will again take place, thereby maintaining the pendulum system in vibration.

The rotation of the plane of oscillation of the system that is recorded in the sand, 122, may be measured at any time by comparing it with the graduations upon the top of the wooden ring, 119. It may possibly be found that the stroke of the suspension plunger, 57, cannot be adjusted quite close enough to insure a constant amplitude of the pendulum system. If this should be the case, although with the threaded shaft, 74, a fine adjustment can be obtained, the regulation should be so made that the amplitude will in time increase slightly, when by manually opening the switch, 154, for a short time the vibrations can be allowed to die down to the original amount. This function may be made automatic if desired. The reason for arranging the secondary circuit to be closed at the end of the pendulum's swing, instead of at its center, which may be accomplished by providing a vertically adjustable metal disc for the needle, 51, to travel over when at the center of its motion, is because the suspension plunger, 57, would have to be normally resting at the lowest point of its stroke in order to properly accelerate the system. This would mean that the bob, 49, would be normally below the ring, 119, and would come in contact with the said ring, 119, either when about to start the pendulum oscillating or when in operation the action of the releasing magnet, 117, should fail for any reason. The contact in the center for this case would have to be comparatively large, for the pendulum bob, 49, would be traveling its fastest when passing over it.

The second method of controlling the releasing magnet, 117, of the suspension mechanism is shown in Fig. 3. This consists in substituting for the sand, 122, some electrically conductive substance, 171, such as powdered graphite, copper or other metal filings. The substance, 171, rests upon a metal annulus, 172, which is placed in a wooden ring, 173. The ring, 173, is mounted upon the posts, 120, of the preceding design, and is graduated into angular degrees. A binding post, 172A, is fastened to the metal annulus, 172. When the pendulum needle, 51, passes through the conductive substance, 171, a furrow will not only be recorded, but an electric contact will be made, which is employed for controlling the releasing magnet, 117. The operation of the pendulum system is analagous to that already described. The wiring, however, is different. The circuit for the starting magnet, 125, consists from the source, 174, which in this case may be a direct-current generator if desired, of the wires, 175 and 176, post, 131, magnet, 125, post, 132, conductor, 177, switch, 140, together with the wires, 178, 179 and 180. For operating the suspension motor, 102, a circuit is provided which is made up from the source, 174, of a conductor, 181, post, 106, motor, 102, post, 107, wire, 182, journal post, 152, switch blade, 151, clip, 150, together with the conductors, 183, 179 and 180.

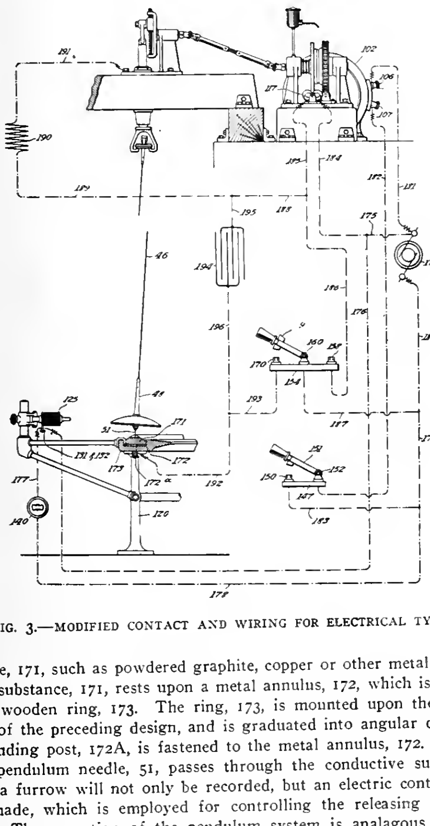

FIG. 3.—MODIFIED CONTACT AND WIRING FOR ELECTRICAL TYPE.

The circuit for manually accelerating the system embodies the source, 174, wires, 175 and 184, releasing magnet, 117, conductors, 185 and 186, clip, 158, switch blade, 159, journal post, 160, together with the wires, 187 and 180. The circuit for automatically controlling the pendulum consists from the source, 174, of the conductors, 175 and 184, releasing magnet, 117, wires, 185, 188 and 189, non-inductive resistance, 190, conductor, 191, suspension apparatus, pendulum wire, 46, post, 48, needle, 51, conductive substance, 171, metal annulus, 172, post, 172A, conductors, 192 and 193, clip, 170, switch blade, 159, journal post, 160, together with the wires, 187 and 180. For the elimination of sparking at the needle, 51, and conductive substance, 171, a condenser, 194, is shunted between the conductors, 189 and 192, by means of two wires, 195 and 196. If desired a relay may be employed in the controlling wiring. This would allow a potential of but several volts from a battery to be used at the needle, 51, and conductive substance, 171, the releasing magnet, 117, being operated directly from the source, 174. Such an arrangement would reduce the arcing to a minimum. Powdered graphite will give satisfactory electrical conductivity, and will probably offer less mechanical resistance to the passage of the needle, 51, through it than metal filings.

In Fig. 4 the third contact arrangement is illustrated for controlling the action of the releasing magnet, 117, of the suspension mechanism. Threaded into the lower end of the pendulum post, 48, is a screw-eye, 197, which has a light metal chain, 198, fastened thereto. The lower end of the chain, 198, is terminated by a platinum rod, 199. Mounted upon the iron posts, 120, of the railing, which is situated below the pendulum system, is a wooden ring, 200, having a groove formed therein for a mercury bath, 201. Resting in the groove in the ring, 200, is a metal annulus, 202, to which a binding post, 202A, is secured. The upper surface of the ring, 200, is provided with angular graduations, 203. The wiring for the pendulum system is the same as in Fig. 3, the contact for the circuit of the releasing magnet, 117, being made by the rod, 199, which dips into the mercury bath, 201, each time it passes the same. The angular change of the pendulum's plane may be noted when the rod, 199, is traveling over the graduations, 203. The chain, 198, and rod, 199, are both made light in order not to disturb the motion of the pendulum. The chain, 198, should also be short for preventing the rod, 199, from swinging unnecessarily.

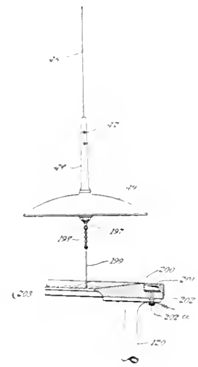

FIG. 4.—MODIFIED CONTACT FOR ELECTRICAL TYPE.

Other contact arrangements may be employed for periodically closing the circuit of the releasing magnet, 117. A flexible copper brush, for example, consisting of a small number of strands of fine wire, may be secured to the under side of the pendulum post, 48, and allowed to lightly pass over the surface of a metal ring when the pendulum is near the ends of its swing. The tilting of the pendulum bob as it swings from side to side may perhaps be made to actuate a mercury contact arrangement, incorporated in the interior of the aforesaid bob. Such a dispensation would embody a small twin concentric pendulum conductor, insulated knife-edge suspension and a bob so constructed that, when it is placed vertically, as would be the case when it is in the middle of its swing, a mercury bath inside of the bob will not short-circuit the two wires of the pendulum conductor. When, however, the bob is at one of the extremities of its amplitude, and is, therefore, in a tilting position, the mercury bath will short-circuit the two pendulum conductors, and thereby allow current to pass to the releasing magnet, 117, of the suspension driving mechanism. Various constructions and adjustments of the pendulum bob may be provided for this purpose. The principle of the coherer, in conjunction with the spark-gap arrangement already described, may possibly be taken advantage of for controlling the magnet, 117.

Let one of the above electrical designs be applied, for example, to a Foucault pendulum system having the dimensions of the original one in the Pantheon at Paris. There the length was approximately 220 ft., with a consequent period of 16.4 seconds or 8.2 seconds for each swing. The amplitude was 10 degrees and the diameter of the sand ring was a trifle over 26 ft. The pendulum bob weighed 61.72 pounds. If the beat of the pendulum is 8.2 seconds the time of one complete turn of the disc, 94, of the suspension driving mechanism would probably be about 7 seconds, or at the rate of 8.57 r.p.m. Inasmuch as the motor, 102, should have a surplus of power, let a ½-hp machine be chosen with a speed of 1,200 r.p.m. If the worm, 97, has a single thread the worm gear, 93, will then have 140 teeth in order to drive the disc, 94, at the desired rate. The worm gear reduction may be readily changed to suit the speed of any alternating or direct-current motor that it may be desired to run on the lighting system available at the locality of mounting. The stroke of the suspension plunger, 57, will have to be experimentally determined, it being probably not over 6 in. for a 200-ft. pendulum. The most advantageous potential for the secondary winding in the step-up transformer, which is employed in the wiring system shown in Fig. 2, may preferably be settled by experiment, it depending upon the air-gap. For an arcing distance of one inch, the secondary voltage would be approximately 20,000 volts. Since, however, the air-gap can be made much less, the ratio of the windings in the transformer need not be so great.

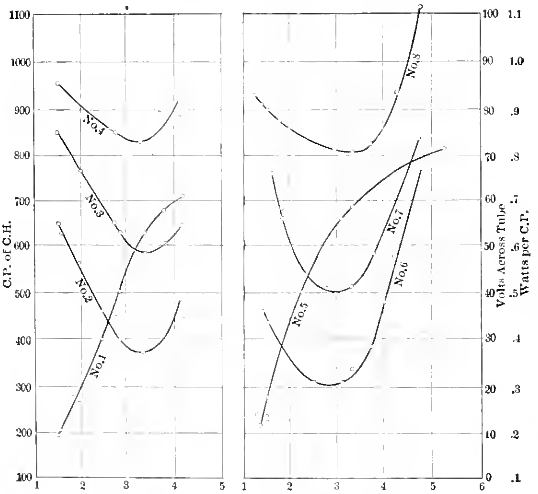
In the communication, mentioned at the beginning of the present paper, it has been suggested that a large Foucault pendulum system be installed at the Exposition in St. Louis. It is believed that such a feature would be an attractive one, and, besides being of physical interest, might form one of the chief exhibits of some college laboratory or physical instrument maker.

Candle-Power Tests of Cooper Hewitt Mercury Vapor Lamp.

By L. A. Freudenberger.

THE tests described below were made at Delaware College, Newark, Del., on a Cooper Hewitt mercury vapor lamp of the type known commercially as Type H-4. The lamp, which is rated at 3 amp. and designed for a 110-volt circuit, has a tube diameter of 1 1/16 in. and a length of arc of 45.67 in.

The lamp was mounted at one end of a five-meter photometer bar and enclosed in a long wooden box at right angles with the axis of the photometer bar. At the middle of the box, in line with the axis of the bar, was a 2 x 2-in. opening. The box was well ventilated so as to give conditions as near normal as possible. The illumination from a two-in. length at the middle of the Cooper Hewitt light was measured and the corresponding candle-power multiplied by the ratio 45.67/2, the length of the light-giving arc to the length of tube used. The lamp and box were inclined to the horizontal plane through the axis of the photometer bar by an angle of 11° 20′. The lamp was compared with a standardized 32-cp incandescent lamp. The screen used was a Lummer-Brodhun. The balance point



FIGS. 1 AND 2.—CANDLE-POWER TESTS OF VAPOR LAMP.

on the photometer bar could easily be located within one centimeter, although the two sides of the screen showed a great contrast in color. In the course of taking readings the screen was, of course, reversed, and the average reading taken.

In Fig. 1 curve 1 represents the variation of candle-power and current; curve 2, the variation of watts in lamp per candle-power; curve 3, the variation of total watts per candle-power with current; curve 4, the variation of current and volts across tube. In Fig. 2 curve 5 represents the variation of candle-power and current; curve 6, the variation of watts in lamp per candle-power and current; curve 7, the variation of total watts per candle-power and current, and curve 8, the variation of current and volts across the tube. In Fig. 3, curve 9 shows the variation of line voltage and current, and curves 10 and 11 the relation of minimum watts per candle-power and current. The curves of Fig. 2 were taken when the lamp was new. The curves of Fig. 1 were taken after the lamp had been running about twenty-four hours.

The reduction in candle-power noted is due to a coating, at first gray and afterward black, which gradually forms all over the inside of the tube. No life tests of the lamps were made, but of two lamps which have been run continuously, one burned out after 800 hours

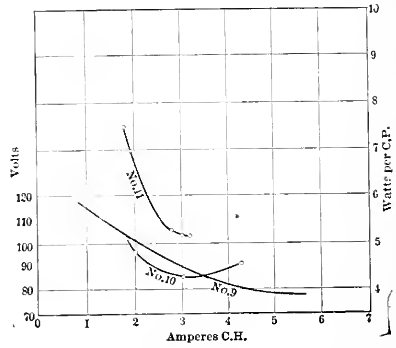


FIG. 3.—CANDLE-POWER TESTS OF VAPOR LAMP.

and the other had not burned out after running 1,000 hours. The lamp that burned out blackened somewhat similar to an incandescent lamp. The immediate failure was due to the impairment of the vacuum, principally through leakage at the leading-in wires.

For all curves the currents were read after the lamp had settled to steady temperature conditions, and the values used as abscissæ. All instruments were calibrated by means of standard cells and standard resistances.

Curve 6 on Fig. 2 was obtained by multiplying volts across the tube by current and dividing by the candle-power corresponding to the current. It represents the watts per candle-power consumed by the lamp itself. Curve No. 7 was obtained by multiplying line volts (assumed constant at 110 volts) by current and dividing by corresponding candle-power. The efficiency in watts per candle-power includes the loss in the ballast resistance in series with the lamp. The curves on Fig. 1 are precisely similar to the curves on Fig. 2, except that they were taken after the lamp had been running about twenty-four hours.

Curve 9 of Fig. 3 merits some explanation. A value of ballast resistance was chosen and the line voltage lowered slowly until the lamp went out. The line voltage and current were taken at the point where the lamp went out and plotted on curve 9. Curves 10 and 11 were obtained by calculating watts per candle-power, using the voltage given by curve 9. Curve 9 shows the minimum line voltage at which it is possible to run the lamp with a certain current. The difference in ordinates between curves 8 or 4 and curve 9 would give the drop in the ballast resistance under this condition.

The above tests were submitted as a thesis in electrical engineering by Mr. F. Schabinger. Thanks are due to the Cooper Hewitt Electric Company for furnishing the lamp, and also to Mr. H. Spoehrer, of the Brooklyn Navy Yard, for furnishing a standardized 32-cp lamp.

Michigan Electric Light Association.

Managers of a number of electric lighting plants in Michigan met in Detroit on June 9 and formed the Michigan Association of Electric Light Managers. Mr. E. F. Phillips, assistant manager of the Edison Illuminating Company, of Detroit, was elected president, and E. S. Hubbell, of Milford, was chosen as secretary. Several committees were appointed to take charge of the work of perfecting plans for future action. The meeting was only preliminary and the association will not get down to business until these committees have reported.

Lost and Unaccounted-for Current.

In our report of the Boston meeting of the National Electric Light Association we referred particularly to the paper by Mr. C. W. Humphrey with the above title, and owing to its exceptional interest it is reprinted below in full, excepting a few of the sheets of tabulations.

The object of the paper was stated to explain in full the calculations of losses, known and unknown, for alternating and direct-current circuits, and to give the records of some of the results obtained and tabulated during the past two years. Most of the data given was compiled from results obtained on the lines of the Denver Gas & Electric Company.

The lines in Denver are now all 2,400-volt, single-phase feeders, but the calculations are approximately the same for all systems of distribution, regardless of voltage, frequency or phase. Even in high-tension transmission lines the same methods may be used, there being no actual losses introduced by inductive drops. Most high-tension lines, however, have integrating wattmeters on both ends of the line. The difference in the readings will indicate the total loss in transmission. This loss may be easily subdivided into resistance losses and transformer losses.

Direct-current losses may be calculated in much the same manner as those of alternating-current circuits, although resistance losses and meter shunt losses are all that must be accounted for. The "drop of potential" method was found the most satisfactory for calculating the line losses, following along the same lines as described for alternating-current circuits (mentioned later). The meter shunt losses were taken care of in the same way as for alternating currents.

The different losses in an alternating-current system may be classified as follows: Transformer iron losses; primary resistance losses; secondary resistance losses; meter shunt losses. For the transformer iron losses there is a card index system consisting of two sets of cards. One set has a card for each transformer on the lines and also those in stock, and shows the date of purchase, where set, manufacturer's number and type, iron and copper losses as shown by test, and also whether or not the transformer has been removed and for what cause, as well as a retest on its iron loss before it is again placed in service. In fact, these cards show the entire history of each transformer from the date of purchase up to the present time. The other set of cards, which is called the feeder index, shows the exact location, make and number of transformer, also the number of feeder on which it is located. These cards are arranged according to location and feeder, while the other index is arranged numerically according to the make and number of the transformer. The records are not as complete as the above statement might seem to imply, due to the fact that these records have all been started within the past two years and do not include full data on transformers purchased prior to that time.

In a great many instances transformer iron losses were tested while in service. This was done in a very unique way and without interruption to service. There is a small testing board, which includes a wattmeter, voltmeter and a small variable resistance. To these instruments are attached two flexible duplex cables of sufficient length to reach from the ground to any transformer on any pole. The primary fuses of the transformer are pulled, the neutral of the secondary is disconnected (that is, if the transformer is on a three-wire network), one side of the secondary is left intact and the other side is cut, and the wattmeter and resistance are inserted in the circuit by means of one of the flexible cables, the other cable being used for pressure wires. The secondaries are kept alive by the other transformers on the system. The resistance is then so adjusted that normal voltage is impressed across the secondaries of the transformer. Readings are then taken on the wattmeter, which indicates approximately the iron loss and may be corrected for instrument losses in the usual way.

There is also kept a transformer record sheet for the purpose of more readily finding the transformer iron losses as soon as possible after the first of the month. These sheets have a line for each day of the month, on which is placed the number of transformers of each size and make according to the different headings. On the extreme right of the sheet is a column for the total transformer iron loss for one day. This represents the total 24-hour loss on that particular feeder, which is the summation of all the individual losses pertaining to the transformers on each line. At the end of the month this last column is totalized, and this represents the total loss for the month on that feeder.

The next known loss to consider is the primary resistance loss. This loss has been more difficult to ascertain correctly and keep up from month to month than any of the other known losses. Four different methods of calculating this loss have been used and each different method and endeavor will be discussed to show the advantages and disadvantages of each.

The first method used was to measure up the length and size of wire in the primary feed, assuming one ampere to be flowing from the station to the first division point in the feeder, then assuming the current to divide proportionally to the connected load in each branch of the feeder; calculating and summing up all losses due to an initial flow of one ampere and using that as a constant. Then ampere-meter readings are taken at short intervals at the station during a period of 24 hours. Each of these readings is then squared and multiplied by the constant. The summation of these losses will give the total primary resistance loss for one day. This method is fairly accurate, but is long and tedious and cannot be relied upon any better than other more simple methods. One point of error in this method is the fact that a suspended wire stretches in course of time, making its cross-section smaller than it was originally and therefore of higher resistance. Joints and junction fuses also introduce errors of more or less magnitude. The results as obtained from this system are always considerably smaller than actual measured results.

The author undertook to accomplish the desired result by placing recording voltmeters at the station and at the center of distribution and then taking the difference between the two readings and multiplying by the load in amperes corresponding to the drop in voltage, and summing up as in the previous method. This would be a very satisfactory method if this drop could be ascertained correctly. A small potential transformer is usually employed for the purpose of stepping the voltage down for the recording voltmeter. The ratio of these transformers, when used on a 2,400-volt feeder, would be 20 to 1. These voltmeters cannot be read with an accuracy closer than one volt; therefore, it means an error which must be multiplied by a constant of 20, and when two voltmeters are used, one at the station and one at the center of distribution, it makes a possible multiplication of an error by a constant of 40. This error amounts to considerable where accuracy is essential.

The next method used was to place an integrating wattmeter in the primary lead just before it begins to feed, running pressure wires for it back to the center of distribution. Readings were taken the first and last of the month, and kilowatt-hour readings obtained subtracted from that obtained on the station wattmeter for the same period. This is a very good method, provided there are no grounds or individual taps taken off between the two wattmeters. If this should be the case, the results obtained might lead to an erroneous impression.

The method finally adopted and now used exclusively is a measured resistance method. With the use of this method the feeder must be shut down at some convenient time, preferably during light load, and the primary fuses of all transformers pulled; that is, all those on the station side of the center of distribution. The primaries are then short-circuited at this point and the resistance of the circuit is measured by the "drop of potential" method with direct current, the direct current being supplied from a separate direct-current machine and the voltage varied so as to permit of a series of readings being taken. The loss is then calculated by means of ampere readings taken at the station at stated intervals, the same as in the first two methods. Or a better way than calculating each particular point is to calculate the losses for different amounts of current and plot a curve of watt loss and primary amperes. This curve also includes the primary copper loss of the transformer on the feeder, full load on the feeder being considered as the sum of the full-load capacities of the different transformers. The readings taken at the station may then be readily run off on this curve and summed up for a period of 24 hours, full-load copper loss of the transformers for the entire feeder being the sum of the individual losses for all transformers on the feeder. The copper losses of a transformer are assumed to be divided equally between the primary and secondary windings. This assumption has been borne out by tests. Fig. 1 is a curve showing the different primary losses as calculated above.

After losses are obtained for a period of one day, the total loss for the month must be calculated. This is done by multiplying the output on the feeder for one day by the number of days in the month and dividing into the total output for the month as obtained on the feeder wattmeter. This result is squared and multiplied by the loss for one day and multiplied by the number of days in the month. These results will be as close as it is possible to calculate them

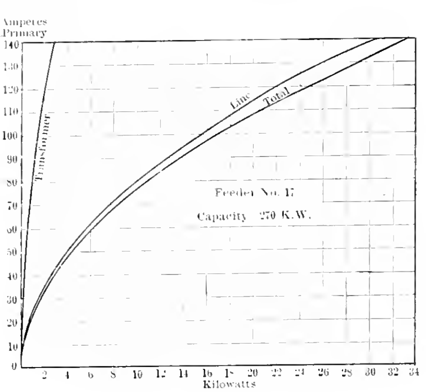

FIG. I.—CURVE OF PRIMARY LOSSES.

and would be very accurate if it were not for the fact that the characteristics of the daily load curve change during the different seasons of the year. The peak is very sharp in the summer with a very small morning peak, while in the winter the peak is quite broad and the morning peak is much more noticeable. For this reason these losses must be recalculated from time to time during the year as these characteristics change. Fig. 2 shows a curve of one of the principal

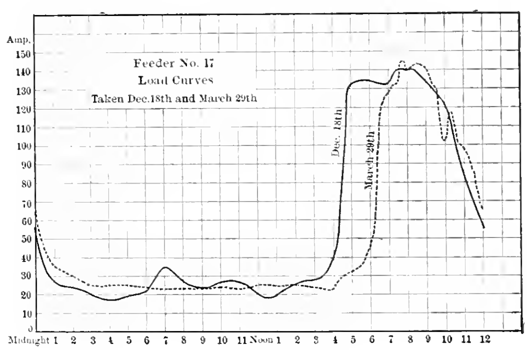

FIG. 2.—LOAD CURVES.

business feeders illustrating these different characteristics. The greater demand shown for March 29 is due to new business on that feeder. Evidence of new business is shown throughout the curve. Both December 18 and March 29 were clear days.

The kilowatt-hours lost due to primary resistance for one year, multiplied by the actual cost of generation, will show whether reinforcements would pay financially and to what extent they might be carried. By cost of generation is means the variable costs, which vary as the output; it does not include any of the fixed expenses.

The secondary resistance losses are somewhat more difficult of accurate calculations. Following is the method which was used exclusively for the three-wire secondary network.

In this calculation some things had to be assumed in order to arrive at results. The total secondary load is assumed to be divided up in proportion to the sizes of the different transformers, one-half the load on each transformer to feed each way, and this amount of current to feed one-fourth the distance between transformers. The assumptions have, however, been verified in each case by the testing of all transformers on the line. This assumption would not hold true, however, before the company began to test the transformers systematically and place them on the lines in accordance with the actual load carried, instead of depending, as is usual, upon the connected load. It was found that the actual load carried varied very widely from that calculated on a basis of connected load.

With these assumptions and the size and length of secondary feeds being known, the losses may be figured for several different amounts of current flowing, and plotted in a curve. The author also figured the loss due to current flowing in the neutral, but this loss was found to be negligible on his system of distribution, due to the fact that the transformers are so evenly balanced that there is a minimum flow of current in the neutral. This is not the case on the majority of distributing systems, as most of the transformers are in the same condition as his were before a systematic test was instituted by means of an instrument termed the "portable line meter." The instrument consists of an ammeter directly calibrated with a small series transformer having a two-piece iron core hinged together so as to permit of its being opened and clasped over a wire at any point. With this instrument he has been enabled to measure the exact load carried on a transformer at any time, also the amount of unbalancing. The loss in the neutral does not vary as the per cent. of unbalancing and is, therefore, inappreciable for small amounts of unbalancing. But in most systems of distribution, where this unbalancing is quite considerable, it becomes an important item. Unbalancing not only increases the losses materially, but also decreases the available capacity of the transformer quite materially. It has been claimed that transformers banked together on a three-wire network would adjust themselves to the total unbalancing of the feeder. This is not true, as the author found transformers of the same make and size on adjoining poles considerably unbalanced on opposite sides; and even in cases where transformers are banked together on the same pole, they will not divide their loads evenly. This was very strikingly illustrated by an occurrence that took place some time ago. During a breakdown in an isolated plant furnishing power for a theatre, the author was called upon to furnish them with light. In order to do this he placed six 10-kw transformers

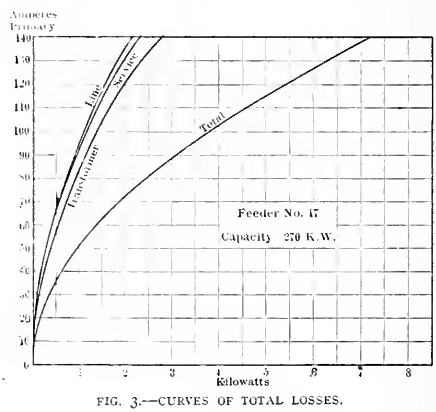

FIG. 3.—CURVES OF TOTAL LOSSES.

and one 20-kw transformer, all of the same make and type, just outside of the building and connected them up for 110 volts, lying them together with a 500,000-cm. cable, which fed the theatre. Following is the average load in amperes on each transformer during operation:

Size.	Load in Amperes at 108 Volts.
10-kw	106 amperes
10-kw	93 amperes
10-kw	130 amperes
10-kw	112 amperes
10-kw	90 amperes
10-kw	90 amperes
20-kw	158 amperes

The author also took into consideration the resistance losses in the service loops. This is taken care of by assuming the secondary load to be equally divided between the different service loops, and taking the average length and size of a service.

The secondary transformer copper loss is taken into consideration in the same way as in the primary losses. A curve is then plotted of the secondary resistance loss, secondary transformer loss and service resistance loss, and then a curve of the total losses is plotted. A sample of one of these curves (Fig. 3) is here shown, watts loss being plotted against primary amperes.

The all-day losses are obtained in the same way as with the primary, using the station ampere readings in the same way; the station ammeter not being relied upon entirely, a standard portable instrument being cut in and used, and the switchboard meters being calibrated at the same time.

The only known loss now left to determine is the meter shunt loss, a loss that one might think at first hardly worth considering, but which is nevertheless of considerable importance and assumes very large proportions in some instances. The loss can be obtained with a greater accuracy and less trouble than any other of the losses. Each different type and size of meter must be tested and the average of a number of different tests taken. The author uses a meter record sheet for the meter losses on each feeder similar to the transformer record sheets. These sheets are kept up from day to day, and at the end of the month the daily losses are summed up, giving the monthly losses. It was found to be much easier to keep up the records in this way from day to day on the different feeders than to wait until the end of the month and then figure up the losses for the past month. It is also the most accurate, and the total losses may be ascertained much more quickly after the first of the month.

The total sales are figured up at the end of each month, and as meters are read in three different divisions at different times, the results do not exactly correspond to the monthly output. The bills for one-third of our consumers cover a period from the first of one month to the first of the next month, one-third from the 10th to the 10th, and one-third from the 20th to the 20th. This variation might amount to considerable in one month, but, as everything is figured accumulative from month to month, the records are very accurate when figured over a space of several months.

After this full explanation of the methods for arriving at the known losses, it will be interesting to note the results obtained in some of the feeders for the past year. There are 24 different feeders, on all of which the above records are kept up from month to month. The author has plotted graphically the losses on some feeders, showing variation of losses from month to month and the gradual but steady decrease in the unknown losses. The first curve (Fig. 4) is

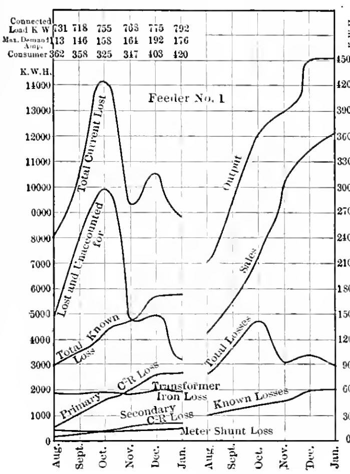

FIG. 4.—CURVES OF FEEDER LOSSES.

that of a residence feeder, which is designated as 1 West. It will be noticed that the output and sales have increased very rapidly. A slight hump will be noticed in the output during October; this is due to some unknown loss, as the curve of sales does not show this characteristic, neither does the curve of known losses. It will be noticed that both the primary and secondary losses show a steady increase due to the increase in the output. The transformer iron loss remains about the same and so do the meter shunt losses. The relation that the sales show to the output varies from 59.3 per cent. to 80.5 per cent., being almost a steady increase from beginning to end, the unknown loss increasing at about the same rate as the output for the first two months, dropping off the next month, and then remaining about the same for the remainder of the period, although both the sales and output increased considerably.

In the accompanying table is a tabulation of an alternating-current feeder for a period of six months. During that time the feeder was changed from a 1,000-volt individual transformer system to a 2,000-volt with a three-wire secondary network, with the exception that there are still some instances where individual transformers are used, due to the sparsely settled territory it covers.

This tabulation shows several very interesting things. During the first two months the individual transformers were done away with

TABLE SHOWING ECONOMY OF THREE-WIRE OVER INDIVIDUAL TRANSFORMER SYSTEM.

Month.	Output.	Sales.	% of output.	Lost and unaccounted for.	% of output.	Transformer iron loss.	% of output.	Primary C A loss.	% of output.	Secondary C A loss.	% of output.	Meter shunt loss.	% of output.	Consumers.
1	19250	7778	40.4	4877	25.4	5940	30.9	222	1.1	138	.7	295	1.6	273
2	15970	6630	41.5	2235	14.1	6475	40.5	229	1.4	92	.6	309	1.9	277
3	20042	10506	52.5	6140	30.6	2560	12.8	373	1.8	150	.7	313	1.6	281
4	35320	21166	60	9417	26.6	2390	6.7	1153	3.3	463	1.3	721	2.1	660
5	40140	28480	71.2	6421	16.1	2441	6.1	1440	3.5	580	1.3	770	1.0	692
6	40940	29113	71.2	6435	15.7	2425	5.9	1503	3.6	605	1.5	859	2.1	771

and replaced with a three-wire network showing a reduction in transformer iron losses from 6,475 kw-hours to 2,560 kw-hours, a decrease of a little over 60 per cent. At the same time the lost and unaccounted-for has taken a jump of nearly 170 per cent. The output and sales increased considerably the same month, due to combining another feeder with this one, adding 387 consumers, which were changed over at the same time to a three-wire distribution. In this instance the sales were increased to nearly double the original amount and the transformer iron loss was decreased to about one-half the original amount. The primary and secondary resistance losses were increased considerably, due to the increase in the output of the feeder.

A complete record sheet is kept for all the rest of the feeders. One of the interesting things on this feeder is that the watts per lamp of output remained about the same for the entire year, while the watts per lamp of sales increased during the same period to nearly double. The sales increased from 41.6 per cent. to 83.5 per cent., the known losses remained about the same, while the unknown losses decreased from 48.4 per cent. of output to only 5.22 per cent.

The lost and unaccounted-for current has been systematically followed up and decreased very materially. This unknown loss is due to leakage through grounds, faulty meter registration, errors and theft. These losses have been plotted graphically as shown in Figs. 5 and 6. Each circuit is tested for grounds, and when found these are traced down and removed.

The greater part of the lost and unaccounted-for current was

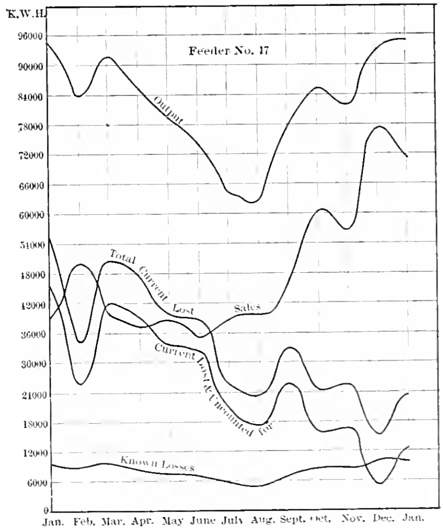

FIG. 5.—CURVES OF CURRENT LOSSES.

found to be due to thefts. These were found by systematic inspection of service loops and interior wiring. Theft of current was found to be done usually by tampering with the wiring, removing pressure wires and jumping out meters, installing lamps ahead of the meter, and in some instances tampering with the meter so as to retard its rotation. Some of these things are very difficult to find, especially in cases of concealed wiring. Some cases of slow meters were found by placing a check meter on the secondary of a transformer feeding a three-wire district, making an isolated district of it by opening up the junction fuses on each side of the transformer. There are quite a number of ampere-hour meters on the circuits, which accounts for some of the lost and unaccounted-for,

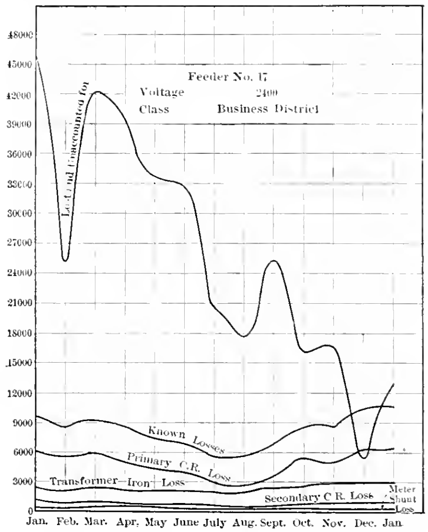

FIG. 6.—CURVES OF CURRENT LOSSES.

as an ampere-hour meter will not start on less than two to four 16-cp lamps. A check meter was placed on one district having nine ampere-hour meters and eleven integrating wattmeters. The results were as follows:

Registered on house meters	331.5	kw-hours
Shunt loss on 11 meters	6.14	kw-hours
Total	337.64	kw-hours
Consump. as shown by check meter	367.3	kw-hours
Loss	29.75	kw-hours, or 8.1 per cent.

About the only absolute method of preventing theft of current, and as yet only adopted in isolated instances, is to place all meters on the pole. This could be accomplished in the business districts of the city by placing a number of meters in one box on a pole and running all services from this box and, where possible, bunching the wires in one cable. This would be especially advantageous where feeding a large number of consumers in a large business block, and where the running of such a cable would not be more objectionable than the present practice of bussing such a building. The principal advantage of such a system would be the impossibility of stealing current from the light company. It should be getting paid for all current distributed and the losses would certainly be materially and permanently decreased.

This completes the discussion of all the principal items relative to the calculations of lost and unaccounted-for current. The importance of an analysis of the output of an electric station can be readily seen by the results given in this paper, and in the majority of instances such an analysis will show such startling results as will lead to investigations that will pay for the time and trouble many times over. In no other way about a central station can money be spent more profitably.

Recent Electrochemical Developments.

Four patents, granted on June 14, refer to battery invention. J. E. Haschke describes mechanical details of construction of a multiple-cell high-voltage battery of that general type in which the cells are put one upon the other like a series of dishes, the walls of the different cells serving as bipolar active plates.

M. Schneider patents mechanical details of a battery in which the positive pole electrode is formed of a number of downwardly converging ribbed lead cones, put one above the other and fastened in the center to a lead core, while the negative pole electrode is formed of a hollow metal cylinder encompassing the positive electrode.

A. J. B. M. Colletas patents a battery in which the active material of the negative pole is a layer of copper hydride (Cu_2H_2) on a copper plate, while the positive electrode is lead peroxide, with sulphuric acid as electrolyte. The electrochemical action during the discharge is the formation of copper sulphate and water and reduction of the lead peroxide to lead oxide.

J. R. Lord patents a general type of battery of which the following combinations may serve as example: The anode is a mixture of zinc and zinc oxide, the electrolyte a gaseous solution of potassium sulphate, and the cathode is copper with the addition of a depolarizer, PbO_2. The theoretical explanations of the inventor are somewhat peculiar.

New Telephone Patents.

A NOVEL RELAY.

Considering the fact that the contact relay has been developed to a point where certain forms have become almost standard, the appearance of an entirely new type may be noted as quite remarkable. Nevertheless, such a new type has appeared, being described in a patent issued to F. R. McBerty, of Evanston, Ill., and assigned by him to the Western Electric Company. This relay is designed for use in strips, the mounting strip, in fact, forming a common return pole piece for the group of relays mounted thereon. Reference may be made to Fig. 1, which shows well the appearance and construction of the relay.

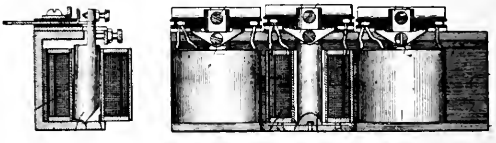

FIG. 1.—M'BERTY RELAY.

As will be noted, the core of the relay is free to oscillate within the coil spool, being supported upon its chisel-edged lower end. The contact circuit is carried through the body of the core, the contact anvil being clamped between insulating strips upon the top of the mounting strip. To avoid "cross-talk" between adjacent coils, these are encased in copper shells. The chief objection, at once apparent, lies in the necessity of removing a whole strip of relays in order to replace the parts of any one in case these relays be mounted in groups according to the present custom.

ELECTROMAGNETIC SIGNALS.

It is quite frequently desirable in telephony that a single signal give two different indications under substantially the same circuit conditions. Under such circumstances it has been necessary to provide auxiliary apparatus and circuits to control the signal proper.

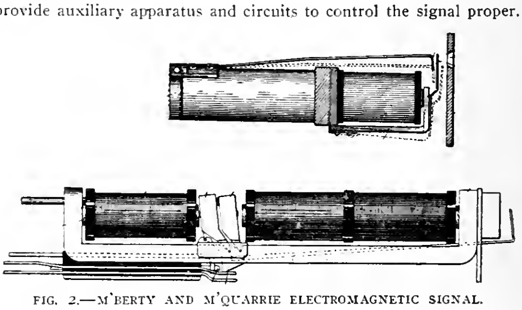

FIG. 2.—M'BERTY AND M'QUARRIE ELECTROMAGNETIC SIGNAL.

There have now appeared patents for several signals in which the secondary controlling device is combined with the signal to form a single piece of apparatus. In two cases the auxiliary device includes a movable shield for signal target, the target being displayed only when it and its movable shield bear the proper relation to a stationary shield. The means employed for controlling the movable shield differ. Both signals described are for use as line signals.

Of these one is shown in the upper part of Fig. 2. As indicated by the dotted lines, when neither coil is energized neither movable part shows. When the rear coil, that connected in the line circuit, is energized, in response to the rising of the hook switch of the subscriber, the target is displayed; and when the operator answers the front coil, in series with one of the jack circuits, becomes energized and elevates the movable shield to obscure the target. This signal is the joint invention of Messrs. F. R. McBerty and J. S. McQuarrie.

In the second line signal the signal and its corresponding jack are mounted together, so that the movable shield may be mechanically elevated by the insertion of a plug. This is the work of the same inventors.

The second type of signal uses another means as an auxiliary control, viz., an auxiliary locking armature. Such a signal is shown in the lower part of Fig. 2. The left-hand armature carries the target. The right-hand armature is the locking one, the weights of the parts being so proportioned that the two armatures acting together will overbalance the target, while the target will overbalance its own armature alone. The target shield is so arranged that the target will be displayed at the window when released by the locking armature. The normal actuating coil is, therefore, that controlling the locking armature. This coil is double-wound for line signals and single-wound for supervisory signals. The left-hand coil is connected with the third wire or local signal circuit to be energized only when a plug is inserted in a jack. The operation is then as follows: When the right-hand or actuating coil is energized the locking armature is pulled up and releases the target to fall before the window. When the operator answers, the restoring coil raises the target into the concealed position. Two patents cover this signal in its various uses, the one granted to F. R. McBerty and F. H. Loveridge and the other to J. S. McQuarrie. The Western Electric Company has obtained all of the above-mentioned patents by assignment.

A NEW LOADING COIL.

Dr. M. I. Pupin has patented a new type of loading coil for use, as the name signifies, in inductively "loading" cable or other conductors to reduce the attenuation of transmitted waves. The coil has a closed magnet circuit, the core being completely covered with windings threading through the aperture. In the specification the requirements for satisfactory loading coils and the limiting values of hysteresis and Foucault current losses in the iron are set forth and formulæ are given for the design of satisfactory coils. The matter is of too technical a nature to warrant detailed consideration here, but those interested will find much of value in the patent. Dr. Pupin has assigned his patent to the American Telephone & Telegraph Company.

LAMP JACK STRIP.

A new lamp jack strip forms the subject of a patent granted to H. P. Clausen, of Chicago. Mr. Clausen builds up his jacks upon a sheet metal strip, no partitions being provided between the lamps. On this account the lamps, except at the extreme end, are each encased in a sleeve of opaque material to prevent any confusion of signals. The opals are mounted permanently in the face of the strip, which face is removable as a whole. It is the inventor's idea to obtain a cheap yet serviceable construction. The patent for this socket strip has been obtained by the American Electric Telephone Company, of Chicago.

STEP-BY-STEP PARTY LINE SYSTEM.

A step-by-step party line system has been invented by E. W. E. Tomson. The system is adapted to permit of a central office selecting at will any station on a line to the exclusion of others. It depends for its operation upon the synchronous action of the instruments at all stations in response to properly timed current impulses sent out by the operator.

FIRE ALARM SYSTEM.

W. L. Denio, of Rochester, N. Y., has made and patented further improvements in his fire alarm system for use in connection with telephone lines. The present devices may be operated manually or by thermostats, to send to the telephone central office a vibratory flash signal appearing at the line lamp. This signal is repeated a number of times to indicate the location of the fire upon the subscriber's premises, the various thermostats being connected in groups to a signal box. A further feature is the automatic clearing of the telephone line for conversation as soon as the fire signal has been sent in.

TELEPHONE RECEIVER.

The last patent for present consideration is one granted to Ernst Gundlach, of Berwyn, Ill., for a telephone receiver and assigned to the American Telephone & Telegraph Company. This receiver is built upon the same general lines as one patented by the same inventor some six months since, and has for its most novel features a spring device for mechanically straining the diaphragm in a direction opposed to the magnetic pull, and the provision of a pole piece mounted at the center of the diaphragm. The core of soft iron but partially fills the spool aperture, the armature extending loosely within the upper portion of it. Great sensitiveness is claimed for this type of receiver.

Municipal Ownership at Ottawa, Can.

A correspondent at Ottawa, Canada, writes us as follows: "In an item taken from the *Canadian News* in your issue of June 4 the following appears: 'The city of Ottawa, some two years ago, voted for a civic lighting system, but at a recent meeting of the city council, in spite of the voice of the citizens, the Ottawa Electric Company was given a contract for street lighting for a period of ten years at $52 per light. Although this is a very favorable contract and a reduction of some $13 per lamp, yet there is much indignation manifested by the ratepayers that their wishes have been disregarded. The report of experts showed that the city could do its own lighting for $38 per lamp per year. Ottawa, therefore, stands to lose $80,000 over the ten years which the contract is to run.' It is quite evident that your correspondent is not only a partisan of municipal ownership, but also in sympathy with the Mayor and the few Aldermen who have been favoring the erection by the city of a distributing station for street lighting; electric power, therefore, to be purchased. The Ottawa Electric Company tendered for city lighting by direct-current enclosed lamps of 480 watts for ten years, at $52 per lamp, all night and every night. This is the cheapest rate in Canada, and it was accepted by the city council, a large majority of whom evidently believed that the city could not do better. Your correspondent would make it appear that this action on the part of the council had aroused public indignation; as a matter of fact, interested Aldermen did cause to be called an indignation meeting to protest against the action of the other Aldermen who did not share their opinions, but this meeting proved a veritable boomerang, ending up by the passing of a resolution by a vote of two to one, approving the action of the majority of the council in giving the contract to this company.

"An expert engineer employed by the city made an estimate of $38 per lamp per year, but other well-known experts employed by other parties showed that the city could not do its own street lighting on the plan proposed for less than $52 per lamp, so that the report that the city stands to lose $80,000 in the ten years is mere conjecture. The item is one of the kind that are dished out regularly by the municipal ownership partisan press, but it is quite misleading."

National Electric Light Association Membership.

At the twenty-seventh convention of the National Electric Light Association, held in Boston, May 24-27, an amendment to the constitution was adopted dividing the membership into six classes, as follows: Class A, Member Companies—Private corporations or individuals engaged in the business of producing and supplying electricity for light, heat or power for commercial or public use. Entrance fee, $25; annual dues for companies in towns of less than 20,000 population, $10; 20,000 to 300,000, $25; over 300,000, $50. Class B Members—Officers or employees of member companies, elected and continued from year to year with the written consent of the member company with whom connected. Entrance fee, $5; annual dues, $5. Class C, Instructors and Teachers of Engineering and Related Sciences—No entrance fee, annual dues, $4. Class D, Associate Member Companies—Electricians, electrical or mechanical engineers, manufacturers, corporations or individuals, who are directly or indirectly interested in advancing the interests of electricity. Entrance fee, $25; annual dues, $2. Class E—Officers and employees of Class D, elected and continued by written consent of the Class D member employer. Entrance fee, $5; dues, $5.

There will also be a class of honorary members without fees or dues.

CURRENT NEWS AND NOTES.

CHEAPER RADIUM.—Dr. George F. Lee, of Philadelphia, declares that he has discovered an electrochemical process of manufacturing radium for less than $500,000 a pound. Dr. Lee says he learned from the Curies that barium and thorium rock particles clung to radium. He set to work to thoroughly analyze these rocks and abstract their luminous properties. He placed the combination of barium and thorium in a box and found, after a time, that they produced a fluorescent substance that would penetrate metal. He states that it will be only a short time before he will be able to produce radium. It is not very clear that Dr. Lee has anything in particular.

ELECTRIC POWER IN SCOTLAND.—Mr. Rufus Fleming, United States Consul at Edinburgh, Scotland, says: "No trade here has a better prospect at this time than that of the electrical engineering firms. The demand for motors and all other electrical apparatus will undoubtedly continue to grow from month to month, and American companies prepared to compete in these lines of manufacture have now their best opportunity. The application of electricity as a motive power in various industries, for urban lighting and traction, as light and power for coal mines and other uses, examples of which are numerous, mark the real dawn of the electric power era in this part of Great Britain. American manufacturers have in the past few years furnished some of the heavy machinery for municipal generating stations and private plants, and also a considerable number of dynamos, motors, etc. American-English concerns have done much in this line—in fact, they seem to be well ahead of all others. Recent developments mean an expanding market, to which our manufacturers of electrical machinery and supplies may find it profitable to devote earnest attention."

LETTER TO THE EDITORS.

The Government and the Fessenden Wireless System.

To the Editors of Electrical World and Engineer:

SIRS:—Will you kindly permit me to make the following corrections to the statements reprinted in your issue of June 22 from the New York *Evening Post,* under the title, "A Government Wireless Mix-up," as some of the statements contained therein would do us considerable injustice unless promptly corrected.

1. The Agricultural Department is not in any tangle with Prof. Fessenden, but on the contrary relations between the Department and Prof. Fessenden are entirely harmonious.

2. The statement that the Agricultural Department now claims, or has ever claimed in the past, to own the system of Prof. Fessenden, is a falsehood manufactured out of the whole cloth. No such claim has ever been made by the Department or any of its officials.

The facts in the case are that after Prof. Fessenden had been developing his system for a year or more in Pittsburg, the attention of the Agricultural Department was attracted by some of the experiments which he had made in operating across the cities of Pittsburg and Allegheny. A contract was, therefore, entered into according to which the Department, in return for the expenditure of some $15,000, obtained the right to use all of Prof. Fessenden's inventions which were invented up to July, 1902, "For its use in receiving meteorological reports and transmitting Weather Bureau information." Subsequently to July, 1902, the development of the system was carried on by Prof. Fessenden at a further cost of over $200,000.

While, therefore, the Weather Bureau has made an extremely advantageous bargain for the Government in securing at cost of manufacture apparatus which would otherwise cost it some $500,000 or $600,000, the Department does not and never has claimed to have any right whatever to the Fessenden system, or any right to use the same for anything except the specific "Transmitting of meteorological reports and Weather Bureau information." According to the contract. "All commercial rights and privileges in connection with this invention are reserved by said Fessenden."

3. This system was not invented by Prof. Fessenden while in the employ of the Agricultural Department. Prof. Fessenden worked on this system for over a year before he entered Government service, and out of the total six years spent in the work but two years were spent in Government service. Also, of the total sum expended in developing the system, less than 7 per cent. was furnished by the Government, the remaining 93 per cent. being furnished by Prof. Fessenden and his partners.

4. The Navy Department is not committed in any way to the Slaby-Arco system. At the time when the Slaby-Arco apparatus was first installed, the Navy Department held that the prices asked by the Marconi and Fessenden Companies were too high, and never made any test of either of these systems. Tests were made of the Braun, Slaby-Arco. Lodge. De Forest and American Wireless systems. As a result, the Slaby-Arco system was adopted, but the fact should be clearly understood that neither the Marconi nor Fessenden apparatus was permitted to enter the competition on account of the prices asked.

The apparatus purchased, i. e., the Slaby-Arco, infringed the patents of both the Fessenden and Marconi Companies, but these companies had no recourse for the following reason:

It is impossible to sue Government Departments except where a contract has been made. This question has been decided several times in the Court of Claims, and though several judges have pointed out the inequity of the situation, the fact remains that the only remedy an inventor has, should the Government decide to use his inventions without paying for them, is by getting a special act of Congress passed. This, of course, practically no company in the early stages of its formation is able to do, and under the present laws Government Departments can and do habitually appropriate the property of inventors, without the inventors being able to obtain any redress.

From one point of view the situation is not as outrageous as it seems to the inventors, for the reason that it is the function of a Department to carry on its work in the most efficient way possible, and it cannot be expected to take up legal questions. Again, in many cases the inventor has a recourse in being able to sue the party who sold the apparatus to the Government, and if the seller is a responsible party can recover damages. Therefore, on the whole there would be no objection to the Departments acting in this way, *provided that they purchased apparatus only from responsible agents inside of the United States, and ones capable of giving bond to pay damages.*

However, this was not the case with the Slaby-Arco apparatus, as the apparatus was purchased abroad through a foreign agent, and imported free of duty. Under these circumstances, in spite of the fact that the Slaby-Arco Company infringed Prof. Fessenden's apparatus in several fundamental points, and in fact was merely a combination of the Fessenden and Marconi apparatus, neither of these companies had any recourse.

These companies, therefore, labored under the peculiar disadvantage that they were competing against a foreign company which manufactured its apparatus abroad where the labor costs less than half what it does in the United States, which had its apparatus introduced in the United States duty free by the Government, and which, by candidly appropriating the Fessenden and Marconi inventions, was thereby relieved of the enormous cost of experimental investigations.

The somewhat ludicrous situation is thus presented of a foreigner who had appropriated the ideas of an American inventor, receiving decorations and grants of large sums of money from his own government, while the American Government was purchasing this pirated apparatus, and introducing it free of duty on the ground that the American inventor asked too much, and in spite of the fact that the American Company had tendered exactly the same class of apparatus.

The situation has, however, improved considerably of late. There is this to be said for the Navy, that when the facts were finally placed plainly before the Department they realized at once the fact that the American company had not received justice in the matter, and it may be stated with some degree of certainty that the American systems will have an opportunity of showing what they can do, and that should any foreign apparatus be bought it will be bought of responsible agents residing in this country, and capable of paying damages should they be assessed against them by a court. The question of which system is to be adopted by the Navy is at the present moment an open question.

5. The Army is not experimenting with a combination of the De Forest and Signal Corps systems. The Signal Corps installed two stations at Forts Wright and Schuyler, and tried a number of

systems, including the Lodge, Slaby-Arco and De Forest. None of these were successful, until the De Forest Company manufactured two liquid barretters of the type invented by Prof. Fessenden, whereupon immediate success was had. The De Forest Company had sold the liquid barretter to General Greely before the National Electric Signaling Company became aware of it, and immediately upon learning of it the National Electric Signaling Company commenced suit against the De Forest Company, but the suit will not come up for hearing before October or November next. General Greely thereupon took the position that he would decline to buy apparatus from any company until the ownership of the patents was decided, and meantime instructed his officers to arrange a system solely with a view to its utmost efficiency, stating that the Department would later compensate the inventors when the ownership of the patents was decided. The system in use by the Army was, therefore, arranged by the officers of the Signal Corps, and is known as the Signal Corps' system. No company has any authorization to use its name in connection with the Alaska apparatus, and in view of the fact that the system embodies the wave chute (rendered necessary by the frozen ground of Alaska), the multiple vertical, the high frequency tuned steel guy supports, the tuned condenser circuit for prolonging the oscillations at the sending end, the liquid barretter, and closed tuned circuit at the receiving end, etc., covered by the Fessenden patents belonging to the National Electric Signaling Company, if the name of any company is used it should be that of the National Electric Signaling Company.

With reference to the ELECTRICAL WORLD AND ENGINEER's editorial on the morality of a government appropriating the wireless business, this company naturally has the same opinion. While there have been many cases where the Government has acted unjustly and improperly, it is not believed that matters have yet got to such a point that a socialistic scheme for stealing property developed at an expense of hundreds of thousands of dollars can be rushed through Congress, either now or for many years to come. When the time comes that the American people are willing to see several hundreds of thousands of young men and girls working for from $3 to $5 a week with the ultimate prospect of just getting enough to pay their board, in order to keep down an annual telegraphic deficit, as is now the case in England and Germany, the times may ripen for such an act. But not now.

NATIONAL ELECTRIC SIGNALING COMPANY,
H. J. GLAUBITZ, *Manager.*

DIGEST OF CURRENT ELECTRICAL LITERATURE.

DYNAMOS, MOTORS AND TRANSFORMERS.

Transformer Oil.—SKINNER.—An illustrated article in which the author discusses the properties required from oil for transformers and describes the methods of testing. Tests of the insulating value of an oil are made by determining its dielectric strength; the general method is to immerse a spark-gap in the oil, the gap being set at a known distance, and to gradually raise the potential until rupture occurs. The author gives very distinct rules on this test, also on the flash and fire test; he discusses evaporation, the deteriorating effect of moisture, the viscosity, the cold test, the color, the detrimental effect of sulphur compounds in the oil, and the formation of deposits. Transformer oil should be a pure mineral oil obtained by fractional distillation of petroleum unmixed with any other substance and without subsequent chemical treatment. The flash test of the oil should not be less than 180° C. (356° F.) and the burning test should not be less than 200° C. (392° F.). The oil must not contain moisture, acid, alkali or sulphur compounds. The oil should not show an evaporation of more than 0.2 per cent. when heated at 100° C. for 8 hours. It is desirable that the oil should be as fluid as possible and that the color be as light as can be obtained in an untreated oil.—*Elec. Club Jour.*, May.

REFERENCES.

Three-Phase Motors.—GROB.—For testing three-phase induction motors it is valuable to have simple and exact methods for determining the efficiency, phase difference, overload capacity, slip, etc., by means of simple measurements. This may be done with the diagrams of Heyland and Ossanna. The author develops a new and relatively simple diagram in which the effect of the ohmic voltage drop is taken into consideration (which was not done in the first Heyland diagram).—*Elek. Zeit.*, June 2.

Induction Motor.—BREGUET.—A mathematical article, illustrated by diagrams, on the Behrend-Blondel-Heyland diagram of induction motors.—*L'Eclairage Elec.*, May 21, 28.

Single-Phase Commutator Motors.—LEHMANN.—A theoretical paper in which he first briefly discusses the windings of such motors and then gives the theory of the repulsion motor.—*L'Eclairage Elec.*, May 28, June 4.

Repulsion Motor.—CARTER.—The first parts of an illustrated serial on the properties of the repulsion motor.—Lond. *Elec. Rev.*, May 27 and June 3.

Railway Motor.—ROBERTSON.—An illustrated article on the winding of a railway motor armature. He describes the construction through its different processes of manufacture, the Westinghouse No. 12A railway motor armature being taken as example.—*Elec. Club Jour.*, May.

Machine Design.—LOEWY.—In a continuation of his illustrated serial on improvements made during 1903 in design of electric machines, he deals with induction motors.—*Zeit. f. Elek.* (Vienna), May 22.

Two-Phase Synchronizer.—PERCY.—A description, with dimensioned drawings, of a two-phase synchronism indicator of the revolving light type.—*Am. Elec.*, June.

LIGHTS AND LIGHTING.

Street Lighting.—HALLBERG.—A full discussion of the system of street lighting by means of small candle-power enclosed arc lamps. They consume about 250 to 300 watts at the arc, and are operated either with direct or alternating current, and are connected either in multiple or in series. The advantages of these four systems are discussed in detail and for parallel connection of the lamps it is shown that the alternating-current system has about 10 per cent. higher efficiency than the direct-current system, but requires the installation of about one-third more in generator and transformer capacities. For series connection of the lamps the alternating-current system is also more efficient than the direct-current system and requires about the same generator capacity. From the central station operator's point of view the series alternating-current system is the most advantageous, the series direct-current system comes next, the multiple alternating-current system third and the multiple direct-current system is last.—*Am. Elec.*, June.

POWER.

Electric Elevator.—JAMES.—An illustrated lecture on the present status of the electric elevator. The direct-current drum type machine, with the most modern method of control, gives very satisfactory results up to a speed of 300 ft. per minute. The cost of maintenance of this machine is reasonable where it receives proper attention, the depreciation being less than 10 per cent. Direct-current electric machines of other types which have been designed to compete directly with the higher speed hydraulic elevators, have not yet come into general use. These machines are too complicated in control and design, too expensive to buy and maintain, and some types have not yet proved that they are entirely reliable in their action. A large number of direct-current machines have been built for speeds of 500 and 600 ft. a minute and are now in successful operation, but they have not so far gained the confidence of the public at large nor the unanimous confidence of elevator engineers. Direct-current electric furnace hoists up to 300 hp have been built and installed to run up an inclined plane 300 or 400 ft. a minute with large loads, and stop automatically at the top and the bottom: these machines have been in operation for several years, and are entirely satisfactory, but their cost is greater than that of steam furnace hoists and for this reason they are not as extensively used as their satisfactory operation warrants. For the induction motor the most promising field in elevator work seems to be in connection with hydraulic installations where the induction motor is used to drive a centrifugal pump. No installations using the centrifugal pump have yet been made, but the matter is in such shape that there probably will be several of them in operation shortly. These motors are being used with success to operate triplex pumps by allowing the motor to run constantly and by-passing the pump automatically when the pressure reaches the desired point.—*Elec. Club Jour.*, May.

Thermal Storage System.—An illustrated article on the Kensington and Notting Hill joint electric works, which supply three-phase currents at 5,000 volts to sub-stations. When extensions became necessary it was found there was room to place a 1,000-kw Parsons turbo generator in the engine room, but an extension of the steam-raising plant was a more difficult problem. It was decided to apply the Druitt Halpin thermal storage system and this experiment has been "conspicuously successful." The main idea of the system is roughly to increase the rating of the boilers at the hours of peak load, by feeding the boiler with water at boiler temperature during those hours, this water having been previously heated to the desired temperature by live steam during the hours preceding the peak hours. Additional boiler plant would, of course, only have been needed to deal with the maximum load for the two or three hours that the peak continues, and thus a substantial increase in the rate of steaming during this period is all that was required. It was found that the expedient answered even better than was anticipated, for an actual increase of boiler efficiency was observed, owing to the improvement in circulation, occasioned probably by the more steady feeding at boiler temperature when the boiler is working at its extreme output. Fig. 1 shows the arrangement adopted. The water tube boilers,

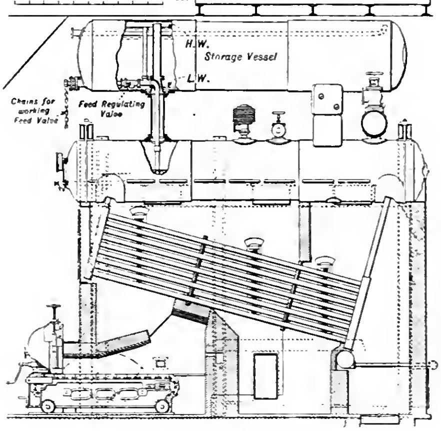

FIG. 1.—THERMAL STORAGE.

which are capable of evaporating 12,000 pounds of water per hour, have two steam and water drums, each 4 ft. in diameter by 24 ft. long, and the thermal storage vessels are placed directly above them, being carried at one end by a 10-in. stand pipe and at the other end by sliding cast-iron saddle pieces. The stand pipe forms a prominent connection to the steam space of the drums of the water tube boilers, so that the temperature and pressure in the boiler and in the thermal storage vessels are always equal. The whole of the feed water, after passing through the feed heaters (heated by the exhaust from the auxiliary engines), and the economizers, is introduced directly into the thermal storage vessel at the top, where, in passing through the steam, it is heated to the full boiler temperature, and it enters the boiler through the feed regulating cock, which is controlled by a spindle passing through a gland in the end plate of the thermal storage vessel. During times of light load the vessel is filled up, and when the heavy load comes on the feed from the pumps is stopped, and the boilers are fed from the water contained in the thermal storage vessels. During time the vessels are being discharged, the boilers are capable of evaporating two to three times the amount of water they can deal with when being fed from the economizers in the ordinary way. The extraordinary gain in the evaporation capacity would, however, not be attainable in the case of every boiler. The boilers at the station in question were originally arranged so that there should be more space for the furnace and freer excess of air to it than in accordance with the usual practice. The boiler tubes were elevated three feet higher than usual, so that the firebrick-lined combustion chamber is formed directly over the fire. There are two firebrick arches instead of one, and the flame-plate division wall between the furnace and the middle chamber is nearer the front of the boiler than usual, so as to raise the temperature and get more work done in the middle chamber.—Lond. *Elec.*, May 27.

Steam Turbine.—PARSONS, STONEY AND MARTIN.—A long illustrated paper read before the (British) Institute of Electrical Engineers on the steam turbine as applied to electrical engineering. The authors discuss at length the development of the Parsons turbine and state that up to the present there are about 600,000 hp of turbines of the Parsons type at work and on order in England and in continental Europe in various sizes ranging up to 7,000 kw.—Lond. *Elec.*, May 27, June 3. In an editorial discussion of the paper it is said that in the discussion G. Insull, of Chicago, gave particulars concerning the 6,000-kw Curtis turbines in one of his Chicago power stations. They were stated to give results 30 per cent. better than the plant in a reciprocating engine station of 17,000 kw. Merz contributed the first independent statement of an efficiency test of a Curtis turbine, namely, a 500-kw set installed at Cork. This set consumed 20.5 pounds of steam per kw-hour, with a vacuum of 27 inches and steam at 150-pounds pressure, superheated 100° F. With a vacuum of 28½ in. and 150° superheat, the steam consumption would have been reduced to less than 19 pounds. It is said that while these results do not excel those obtained with the Parsons turbine under similar conditions, they show that there is not much to choose between the two types as far as steam consumption is concerned; according to Stoney the floor space equipment as well as the capital cost is about the same in each case.—Lond. *Elec. Rev.*, May 27.

Oil Separator.—An illustrated description of an electrical oil separator used at the Leicester electric plant for effectively removing oil from the air pump discharge. There are two large wooden tanks, each divided into five compartments, and each compartment accommodates 10 plain sheet-iron plates ¼ in. thick. All the compartments are connected up in series across a 500-volt circuit and there are five plates in parallel. The liquid to be treated is divided into two streams at one end of the tanks. It then passes into the tanks and through each set of compartments in five parallel streams. Alternate plates are cut so that liquid passes first under one plate and then over the next and so on, so that the circulation is very thorough. The Leicester plant is capable of dealing with 6,000 gallons per hour and requires 12 amp. at 500 volts. The sheet-iron plates last from two to three years. After working for a certain time, they become coated with a deposit which is easily removable by causing the current to pass through the tanks in opposite directions. The deposit then rises to the surface and is cleaned off. This is practically all the attention which the process requires. The air pump discharge water is almost an electric insulator and it is necessary to add a minute quantity of ordinary water. The action of the current is to cause the emulsified oil to coalesce, and when the liquid has subsequently passed through a mechanical filter, there is no difficulty whatever in catching the particles of oil, thus allowing the remaining water, which is exceptionally pure, to pass to the hot well. The separator can be used in conjunction with any type of filter.—Lond. *Elec.*, May 27.

Electric Installation of Mines.—HOSEA.—An illustrated description of the plant of the Colorado Fuel & Iron Company at Primero. The power plant contains two 120-kw, 500-volt electric generators which furnish current for the inside haulage and for the operation of the elevators, screens and box car loaders at the tipple. They are wound for 500 volts and over-compounded 10 per cent. For hauling electric locomotives are provided with three 500-volt motors and equipped with series parallel control. They are capable of hauling a load of 228 tons on a level at a speed of six to 10 miles per hour.—*Mines & Minerals*, June.

REFERENCE.

Turbo-Generator.—WOODBURY.—An illustrated article on the test of a 5,500-kw turbo-generator, being the first of eight built for a

London traction company. It gives three-phase currents at 11,000 volts and 33 cycles and runs at a speed of 1,000 r.p.m.—*Elec. Club Jour.*, May.

TRACTION.

Single-Phase Traction.—An editorial referring to a recent article of Blanck on single-phase traction. It is further pointed out that the question of track equipment has received not enough attention. The question is whether the ultimate standard practice will be to feed the motor cars or locomotives direct from the high-tension line or from a third rail supplied from transformers distributed along the line. A system of the former type is that of the Oerlikon Company. The principle of this system is that the current-collecting device ought to follow the trolley wire and not vice versa; this makes a cheap and safe overhead construction possible. One of its weak points appears to be the shifting arrangement for the current-collecting device as a whole, which is necessary for avoiding obstructions offered to it on the line, such as tunnels, bridges with small clearances, lamp posts, etc., in stations. Concerning the Ward Leonard single-phase traction system, it is thought that this method in which the locomotive carries a sub-station in addition to its driving motors is not destined to be more popular than the Heyman locomotive in which the whole generating station was placed on the locomotive.—Lond. *Elec.*, May 27.

Tractive Resistance on Various Roads.—A note giving some figures on the tractive resistance on various roads, taken from a pamphlet of Max Schiemann. The tractive resistance on railways is from 9 to 18 pounds per ton, on tramways from 26 to 33 pounds, on good stone pavement from 44 to 55 pounds, on bad stone pavement from 66 to 78 pounds, on good macadam from 44 to 67 pounds, on bad macadam from 77 to 100 pounds, and on sand roads from 130 to 220 pounds.—Lond. *Elec.*, May 27.

REFERENCE.

Overhead Tramway Construction.—An article giving practical rules on the design, selection, arrangement and erection of overhead line material. The author deals especially with poles and line insulators.—Lond. *Elec. Rev.*, May 27.

INSTALLATIONS, SYSTEMS AND APPLIANCES.

Earthing Neutral Point of a Star-Connected, Three-Phase System.—TATLOW.—An abstract of a paper read before the Dublin local section of the (British) Institute of Electrical Engineers. He suggested an explanation for the fact that comparatively large currents which cannot be attributed to faulty insulation have been observed in the wire earthing the star connection of the three-phase alternators working in a Dublin station. He shows that the harmonic pressures of three times (or multiples of three times) the mean frequency are the same in magnitude and direction in all the three phases at any moment, whereas the fundamental and the other harmonics differ by 120° in phase in each of the three phases. It follows that in a mesh-connected winding, harmonic pressures of three times or $3n$ times the fundamental frequency, will, if present, add together and drive idle currents round the mesh, while the fundamental and remaining harmonics form balanced sets, the sum of the three pressures due to any of them taken round the mesh being zero at any moment. In the case of a star-connected winding these harmonics of the third order will tend to drive current into or out of the star point equally in all the three windings at any moment, and therefore they will be balanced, and, as far as pressures between any pair of the three wires coming from the machine are concerned, harmonics of the third order are eliminated by the star connection, and should not appear in the pressure wave. They would, however, appear in the pressure wave taken between any of the three leads and the neutral point if they happen to be set up in the windings, and the waves of pressure between lead and lead and between any lead and the neutral point would differ in form. Now, if the star point of the three-phase generator is earthed, and the three leads bringing current from the machine are in the form of a three-core, lead-sheathed cable, these harmonics of the third order will give rise to a capacity current flowing to earth from the neutral point and charging the sheath of the cable. The main potential of the three cores is not zero, but a fluctuating quantity which will give rise to a capacity current depending on the capacity between the three cores taken together and the sheath. In the Dublin cables the capacity of the two cables in parallel amounts to approximately 1.5 microfarads, and the author says that currents in the earth wire of the star of the order of one ampere or more might be expected. He expects to test his theory by bringing a coil connected to a telephone near to the earth wire, and observing the pitch of the note in the telephone.—Lond. *Elec.*, May 27.

Reverse-Current Relay.—An illustrated description of a reverse-current relay for use on direct-current circuits made by a British company. It is a moving coil polarized relay. The moving coil is operated by the fall of potential across the ammeter shunt. With current in the forward direction, the contact carried by the moving coil is held against the stop, but the effect of a reverse current, whose magnitude may be determined by a controlling spring, is to cause the moving coil to rotate and make contact in an auxiliary circuit. This auxiliary circuit contains eight Leclanche cells, and on being completed causes a small electromagnet to attract its armature. This latter closes a pair of heavy carbon contacts which complete the circuit of the tripping coil of the circuit-breaker. The object of the auxiliary circuit is to obviate sparking due to the induction of the trip coil at the necessarily light contacts carried by the moving part of the relay proper. The trip coil is connected across the bus-bars, and is constructed in such a manner that even if the bus-bar voltage should fall to ⅙ of its normal value it would be sufficiently strong to open the circuit-breaker. The connections are so made that a colored lamp is lighted immediately the relay operates, thus indicating at a distance which circuit-breaker has operated. The relay is provided with a push-button and on pressing this the device is caused to work and the circuit-breaker to open.—Lond. *Elec.*, May 27.

WIRES, WIRING AND CONDUITS.

Cable Calculator.—An illustrated description of the Callender cable calculator, designed by Hastings for the purpose of easily determining the size of conductor which should be used under any given conditions. The apparatus is made up of a series of discs mounted upon a common spindle, each having a logarithmic scale upon its periphery. There are six factors which determine the size of the cable, viz.: power, distance, difference of potential, power factor, loss per cent. allowed, and the system of distribution employed. In the apparatus each of these factors is represented by a disc, and the seventh disc, which is fixed to the shaft, accumulates the sum of the movements of the other discs, thereby giving immediately the result of the conditions under which the cable has to work.—Lond. *Elec.*, May 27.

REFERENCE.

Telephone Cables.—SCHMIDT.—An illustrated article on the manufacture of multicore telephone cables with air insulation.—*Zeit. f. Elek.*, (Vienna), May 29.

ELECTRO-PHYSICS AND MAGNETISM.

Stationary Electric Waves.—FLEMING.—A description of an elaborate apparatus exhibited at a recent Royal Society conversazione for the study of stationary electric waves on spiral wires. The apparatus consists of a long solenoid of silk-covered wire, having 5,000 turns and a total length of 643 meters. This solenoid has parallel to it an adjustable earth wire and a divided scale. The solenoid is connected to one point on an oscillatory electric circuit, consisting of a couple of Leyden jars, having a capacity of 0.00068 microfarads, an adjustable inductance between 0 and 230 microhenrys and a silent discharger. When oscillations are set up in this circuit by induction coil discharges and the frequency adjusted, stationary electric waves are started in the solenoid. The position of the loops and nodes is ascertained by the use of a series of carbon dioxide vacuum tubes. The position of the first node is always well defined. According to the theory the distance from the end of the solenoid to the first node should be to the distance between the first and second nodes as 1 to 2.5, and the distance between the first and second nodes should be half the wave length. Experiments with the apparatus gave a mean value of 1 to 2.4 for the above ratio. The inductance of the long spiral is 100 microhenrys per centimeter of length and its capacity is 26×10^{-8} of a microfarad per centimeter of length. From these data it is found that the velocity of the wave along the spiral is about 196 centimeters per second. From the wave lengths experimentally determined, the corresponding frequencies are then found, and these accord substantially with the frequencies as calculated.—Lond. *Elec. Rev.*, May 27.

Radiographs.—D'ARSONVAL.—A paper giving a series of radiographs and showing how they can be produced by the same tube in an identical manner after a considerable interval of time and after using the same tube for various purposes in the meantime. He uses a milliammeter specially constructed by Gaiffe, in conjunction with an alternating-current transformer, raising the voltage from 110 to 60,000. There is also a rheostat and a voltmeter on the primary from which the effective voltage in the secondary may be determined. The current is taken from the supply network. The rest of the arrangement is that designed by Villard. The special milliammeter is only in circuit with the X-ray tube. The radiographs reproduced show that the quantity and quality of the radiation were the same in every case. A given tube may always be brought back to the same conditions of emission. When the pressure is the same, the intensity of the radiation is proportional to the current strength. The new apparatus enables radiographers to repeat any exposure under precisely the same conditions.—*Comptes Rendus,* May 9, Lond. *Elec.,* May 27.

Penetrating Radium Rays.—Paschen.—An account of an investigation in which he found that the γ rays, or penetrating radium rays, are not analogous to Röntgen rays, but are cathode rays or electrons moving with the velocity of light. If radium bromide is enclosed in a continuous casing of lead 1 cm. thick, the γ rays are capable of penetrating that thickness of lead, but the other radium rays are not. In spite of the packing, the positive charge of the radium preparation increases steadily by several volts per minute, which can only be due to the fact that the escaping γ rays carry a negative charge with them.—*Ann. der Phys.,* No. 6; abstracted Lond. *Elec.,* May 27.

Thermoelectricity.—Deguisne.—An account of some experiments in which a copper wire was heated for a distance of about 1 cm. to red heat by means of a Bunsen burner. If the burner is then moved along the wire in the one or the other direction for about ½ cm., an e.m.f. of some microvolts is measured, the direction of the current being in the direction of the movement of the burner. An e.m.f. is also obtained if two free wire ends of the same material, one of which has been preheated, are brought into contact. The author explains his results as follows: By first heating the wire at one place its structure at this place is changed and the wire becomes softer at this point. If the burner is kept at rest, the two points in which the soft wire is in contact with the other wire are of the same temperature and, therefore, no thermo-e.m.f. is observed. If the flame is moved to one side, a difference of temperature is produced between the two contact points and a thermo-e.m.f. is produced.—*Elek. Zeit.,* May 26.

REFERENCES.

Dielectric Constant of Water.—Vonwiller.—An account of the experimental investigation of the variation of the dielectric constant of water with the temperature in the neighborhood of 4° C. Thwing had found a critical point at 4° C., the dielectric constant rising to a maximum value at that point and then decreasing with rising temperature. The present investigator could not find any indication of the large effect observed by Thwing at this temperature.—*Phil. Mag.,* June.

Röntgen Rays in a Magnetic Field.—Walter.—An account of an experimental investigation in which he proved that if Röntgen rays pass through a unit magnetic field, or a field about six times as strong as the earth's horizontal magnetic force in our latitude, the radius of curvature of the rays, if not infinite, is certainly larger than the distance of the moon from the earth. This is another confirmation of the undulatory character of the Röntgen rays.—*Ann. der Phys.,* No. 6; Lond. *Elec.,* May 27.

Radioactivity.—P. Curie.—The first part of an article giving a summary of our present knowledge of radioactivity, with special reference to the most recent investigations.—*Phys. Zeit.,* June 1.

Units, Measurements and Instruments.

Units.—Robertson.—A communication on the completion of the practical system of electrical units. As was recently noticed in the Digest, he has suggested a system which involves getting rid of the 4π in certain equations by including it in the numerical value for μ, and the taking there of another factor, 10^7, in order to make the meter and kilogram consistent with the ampere, volt, ohm. He claims that his system is put forward as being both final and practical. It does not alter any of the given electrical units and it gives simple powers of 10 as the converting factors for the c.g.s. units of all non-electrical qualities. He emphasizes that in the present state of our knowledge there must be four fundamentals in a system of electrical units, and there is no reason why we should expect to reduce this number.. We know that the square root of the product of the electric inductive capacity and the magnetic permeability is the reciprocal of a velocity, but this only enables us to express one of these in terms of the other and length, time, mass.—Lond. *Elec.,* May 27.

System of Units.—Emde.—A very long paper read before the Berlin Electrical Society. A system of units has to fulfill the purpose of enabling the facts to be described in the simplest way. The author first gives a cursory review of the facts of electricity and magnetism and then discusses the dimensions of the various quantities and the various systems of units which have been proposed. He does not himself make proposals, but gives a very full review of the various systems of units proposed, partly with the aid of diagrams and formulas. Concerning Fessenden's proposal to make the ampere-turn the unit of m.m.f., he says that this means simply to sanction in theory what is already done by everybody in practice. The author discusses at great length the proposals made by Giorgi. In the discussion which followed Hagen claimed that international electrical congresses, like that at St. Louis, are not the place to decide about such questions, since the majority of the members of the congress would not be competent to discuss them; he thinks that such a question should be discussed exclusively by official delegates of the various countries. Goerges does not like the adoption of the ampere-turn as the unit of m.m.f., since there are m.m.f.'s which are not due to electric currents; he has always considered the distinction between m.m.f. and number of ampere-turns to be very useful. Emde called attention to the double sense in which the term kg. is used, sometimes as a unit of mass and sometimes as a unit of weight. He suggests the name hyl for the unit of mass.—*Elek. Zeit.,* May 26.

Variable Resistance.—An illustrated description of a simple and convenient arrangement for obtaining a variable resistance to work in conjunction with banks of lamps or resistance racks to give finer regulation of current. As shown in Fig. 2, five incandescent lamps

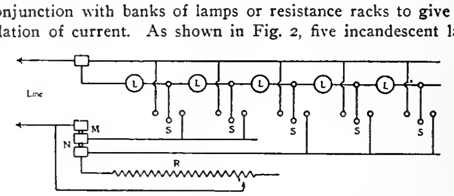

FIG. 2.—VARIABLE RESISTANCE.

are connected in series with the hinge jaws of the single-pole, double-throw switches. A german-silver resistance coil, with sliding contact, is connected by blocks at M or N, so that it may be used in series with various combinations of the lamps. The end lamp has twice the resistance of any of the others. If the coil be designed to have a resistance equal to that of a lamp, it will be seen that by proper arrangements of the switches and adjustments of the coil a great number of values of resistance may be obtained, which will range from a maximum, when the lamps are in multiple, to a minimum when the lamps are in series. Somewhat greater flexibility is attained by using two coils instead of one and connecting them in series or parallel as the occasion may require. This device is especially desirable for use in testing and calibrating instruments where very small currents are often used and where small changes of current values are necessary.—*Elec. Club Jour.,* May.

REFERENCES.

Measuring Small Capacities with an Adjustable Standard Capacity.—Gerdien.—An illustrated article in which the author describes an adjustable condenser which he has found useful as a standard instrument. It is essentially a combination of two coaxial cylinders, one placed in the other, the capacity being changed by pushing the inner cylinder more or less into the outer one. He then describes a simple method for using this standard condenser for measurements of small capacities.—*Phys. Zeit.,* June 1.

Electric Micrometer.—A note on an electric micrometer exhibited by Crompton at the recent Royal Society conversazione for measuring screws or other small mechanical parts. It is arranged so that a contact of the part with the micrometer screw is detected by the click of a telephone in circuit with the parts. This method is extremely delicate and very easily manipulated.—Lond. *Elec. Rev.*, May 27.

Measuring Currents in a Three-Phase System.—An illustrated note on a method used in switchboard wiring where it is desired to measure the currents in a three-phase system by means of one ammeter and only two series transformers, instead of three, which are usually necessary.—*Elec. Club Jour.*, May.

TELEGRAPHY, TELEPHONY AND SIGNALS.

Magnetic Wave Detectors.—ARNO.—An illustrated description of a rotary-field detector of Hertzian waves. Ferraris has demonstrated that an iron cylinder is caused to rotate when placed in a rotary magnetic field, even when the cylinder is sectioned in such a manner that no Foucault currents can be induced in it; the rotation is then due to magnetic hysteresis, i. e., to the drag caused by the magnetization of the iron lagging behind the rotation of the magnetic field. If the iron cylinder is subjected to the action of a rotary field and at the same time to a high-frequency oscillating field, then its behavior indicates the existence of the latter. He proved this by suspending in a rotary field, by means of bifilar suspension, a disc consisting of a mixture of iron and steel powder and paraffin wax, on which was wound a coil having one end connected to earth and the other to the vertical air wire. After having read by means of mirror and scale the deviation of the disc under the action of the rotary field alone, the oscillator was brought into action, and a distinct increase in the deviation of the disc was observed. In order to increase the sensibility of the apparatus he now uses the arrangement shown in Fig. 3. The initial deviation of the moving member

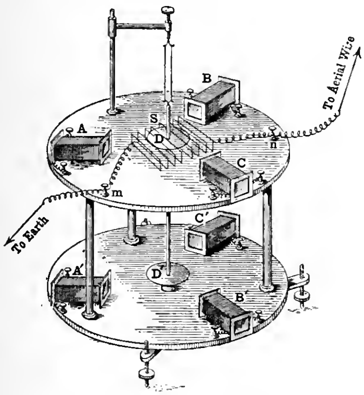

FIG. 3.—FERRARIS FIELD DETECTOR.

is always zero, whatever the intensity of the revolving field; for this purpose two perfectly equal discs, D and D^1, of magnetic dielectric material are suspended in two magnetic fields of the same intensity revolving in opposite directions; these two fields are obtained by means of the electromagnets, A, B, C, A^1, B^1, C^1, inserted in the three circuits of the three-phase system. Only one of the two discs is placed within the spiral, S, by which the terminals, m, n, are connected to earth and to the vertical air wire.—Lond. *Elec.*, June 3.

Duplex Telegraphy.—A note stating that a telegraph line from Vienna to Czernowitz about 650 miles long, had gradually become inadequate for the increasing traffic from Vienna to the southeast of Europe. As a second line would have cost about $62,500, it was decided, in spite of the fact that the line consists of iron wire, to try the differential system of duplex telegraphy, the cost of which amounted to but $1,040. The experiment succeeded and the system has now been working satisfactorily for some weeks.—Lond. *Elec.*, May 27.

Electrical Laboratory.—HOCHENEGG.—A fully illustrated description of the Electrical Laboratory at the Institute of Technology of Vienna. Three-phase and direct currents are available, the latter being supplied partly from the outside mains and partly from a storage battery. For the illumination of the lecture room 48 osmium lamps, each of 50 candles, are arranged in the ceiling, while the demonstrating table is illuminated by thirty-six ordinary candle lamps of 16 cp. This method of illumination is said to be very effective.—*Zeit. f. Elek.* (Vienna), May 1.

The Young Engineer.—SCOTT.—A reprint of the major portion of his address to the graduating class of 1903 of the Stevens Institute of Technology, on the young engineer and his opportunity.—*Elec. Club Jour.*, May.

New Books.

READY REFERENCE TABLES. Vol. I: Conversion Tables. By Carl Hering. New York: John Wiley & Sons. 196 pages. Price, $2.50.

This valuable reference book is very appropriately introduced by a quotation from Lord Kelvin as follows: "I look upon our English system as a wickedly brain-destroying piece of bondage under which we suffer." While many of the tables in the book would not be rendered superfluous if the metric system were in universal use, yet a glance through the pages reveals a distressing situation incident to the use of the English system of weights and measures. It is really refreshing when one comes to the section of the book devoted to electrical units and measurements which, forming part of the broad metric system, are naturally not handicapped with the burden of empiric, arbitrary relations which the English system imposes in other departments of applied science.

In this first volume all the various measures used in practice, and more especially those employed by engineers and physicists, are given, with their values expressed in terms of correlated measures likely to be used in practice. The reciprocals are also given, thus enabling every calculation involved in the conversion of one measure into another to be reduced to a single multiplication. The plan of the work involves the inclusion of every unit of measure used in practice, besides many that are now obsolete, but occasionally met with. Several hundred of the more usual foreign units or measures are also included.

A valuable feature of the book is that the conversion factors have not been merely compiled, but were all specially re-calculated for this volume under the direction of the author, from the exact legal values or the most authoritative data attainable where no legal value exists. In the preface it is stated that the calculations were in many cases made by two entirely different methods and the resultant values checked and cross-checked, often several times. In some cases the values were checked by the original authorities after the pages were electrotyped. A useful feature consists of approximate figures for values to the nearest fraction or other abbreviated number easily memorized, the approximations all being within two per cent. In many of the tables the logarithms of the values to seven places are given.

The introduction deals with the inter-relation of units, distinction between units and quantities, the absolute systems of units and dimensional formulas. The main body of the book is introduced by tables giving the physical quantities and relations in use, with their names, symbols, derivation and dimensional formulas and corresponding c.g.s. unit, these tables being an extension of a similar table which received official endorsement by the Chicago International Electrical Congress of 1893. Then follow the tables of conversion factors, which cover a wide range beyond the fundamentals of length, surface, volume and mass. Among the many headings in addition to the last-mentioned are pressures, energy, tractive force and energy, power, moments of inertia, angular velocity, linear and angular acceleration, plane and solid angles, water discharges, electric and magnetic units, photometric units and thermometer scales. The final pages deal with miscellaneous subjects, such as money, paper measure, scales of maps and drawings, useful functions of π, useful numbers, systems of logarithms, acceleration of gravity, mechanical equivalent of heat, specific heat of water, etc.

The sections on electric and magnetic units supply a great need, and give information that otherwise would have to be gathered from numerous sources, some not easily accessible. An admirable feature consists in numerous formulas giving the various relations of each quantity and the other electrical and magnetic quantities, including the numerical coefficient if there is one. For example, under ohms are given the relations with volts, amperes, coulombs, watts, joules, henries, maxwells, impedance, reactance, susceptance, admittance and frequency, thus enabling the ohms to be calculated from any two or more of these. In the same section are given many numerical values, accompanied by logarithms, of units of specific resistance, such as the mil-foot, circular millimeter-per-meter, square millimeter-per-meter, and following is a table giving the resistivity of copper and mercury in all these units and in others. Conductance, admittance and susceptance are similarly treated.

Under e.m.f. are given the values, in terms of the "international" volt, of the several volts that have been in use, and also the voltage of the several standard cells, with tables of values for the Clark and the Weston cells at different temperatures. All of the electrical and magnetic quantities are treated exhaustively along the above lines, the data collected relating to each being much more inclusive than has ever heretofore been attempted. Sections that will be of particular interest are those considering exhaustively the magnetic units and quantities, since these are given scant mention in most books.

The subject of photometric units is excellently treated under the main heads of intensity of light, flux of light, illumination, quantity of light and light efficiency, all of the many units used, as well as the system of units proposed by Blondel, being defined and inter-related quantitatively. The table giving the values of each of the second thermometer scales in terms of the others, from absolute zero to the temperature of the sun, is exceptionally interesting on account of including entries of the freezing, boiling or melting points of some hundreds of substances.

The book is prefaced by a table of symbols and abbreviations used in the text containing more than 300 entries, which should serve as an object lesson teaching the dire necessity of a uniform system of scientific and engineering notation. Though the price at which the work is published is remarkably high for a book of the size, yet it is well nigh indispensable to all who want to have at hand for ready reference the measures and values used in the physical engineering sciences. It is sincerely to be hoped that the author will supplement the volume by another giving tables of fundamental physical data, such as resistivities of solutions and metals and particularly of alloys, electrochemical equivalents, thermoelectric e.m.f's and e.m.f's of combinations of the various metals and electrolytes, Berthelot's heats of reaction, specific inductive capacities, and various other magnetic and electrical constants, many of which are not readily accessible, or when given in some publications are of doubtful authenticity.

Convention of Railway Telegraph Superintendents.

The twenty-third annual convention of the Association of Railway Telegraph Superintendents was held at Hotel English, Indianapolis, Ind., June 15 and 16. The meeting was called to order by President Charles S. Rhoads, who, in a brief address, congratulated the Association on its prosperity which, he said, is more marked at this time than at any other period in its history. He introduced the Hon. J. W. Holzman, Mayor of Indianapolis, who extended to the delegates a hearty welcome to the city. His Honor stated that he would not tender the keys of the city, as is usual on such occasions, because the gates would be left wide open during the sessions of the convention and no keys were necessary. He spoke a good word for the city of Indianapolis and the character of its citizens. Mr. Charles Selden, on behalf of the Association, responded to the Mayor's address, thanking the latter for his kind expressions of welcome.

After the transaction of some routine business several active, associate and honorary members were elected. Letters and telegrams of regret at inability to be present were read from several of the members, including Mr. Thomas A. Edison, and L. W. Stanton, of Cleveland. The morning session was concluded by the reading of the reports of the secretary and treasurer.

At the afternoon session a paper entitled "The Telephone in Railway Service" was read by Mr. A. G. Francis, railroad agent of the Chicago Telephone Company. Mr. Francis discussed the economy, development and equipment of railway signal towers. In the discussion of the paper it was brought out that railroad trains on many roads are being moved successfully on telephonic orders, and that up to the present time not a single accident, traceable to such orders, has been recorded. The subject of the paper was referred to the committee with instructions to bring the matter before the American Railway Association for the purpose of formulating orders permitting the movement of trains on telephonic orders.

Mr. F. G. Sherman, of the Central Railroad of New Jersey, read a paper entitled "The Economic Use of the Commercial Telegraph by Holders of Telegraph Franks Issued on Account of Railroad Contracts." In the discussion of this paper many abuses of the articles of contract were referred to.

At the evening session the first business was a paper by Mr. J. B. Taltavall, of New York, entitled "The Telegraph Operator in the Railroad Service." In the discussion that followed it was shown how improvements in the operation of the railroad telegraph system could be made without increasing operating expenses; and many of the members gave an account of the methods adopted by their respective roads as tending to improve the worth of the individual operator.

Mr. William Kline, of Toledo, Ohio, described the combination telephone system operated by nine of the railroads entering that city, which was used for the purpose of facilitating the exchange of business between the different roads. He stated that the results had so far been most satisfactory and that the movement of traffic had been greatly expedited. Along the same general line Mr. E. P. Griffith, of the Erie Railroad, read an exhaustive report on the subject of "Composite Circuits," which gave a list of the railroads in the United States at present using such circuits; also the results attained in each case. The interest of the subject to the members was evidenced by the fact that the discussion lasted until 10.30 o'clock, when the meeting adjourned until Thursday, June 16.

At the Thursday session the first business transacted was the election of officers and the selection of a place for the next meeting. The election resulted as follows: President, Mr. H. C. Hope, Chicago, Minneapolis & Omaha Railway, St. Paul, Minn.; vice-president, E. E. Torrey, Mobile & Ohio Railroad, Jackson, Tenn. Mr. P. W. Drew, of the Wisconsin Central Railway, Milwaukee, Wis., was re-elected secretary-treasurer. It was decided to hold the next convention at Chattanooga, Tenn., on the third Wednesday of May, 1905. President-elect Hope then assumed the chair and thanked the convention for the honor conferred upon him.

A paper by Mr. L. S. Wells, of the Long Island Railroad Company, on the subject of "The Typewriter in the Telephone Service," was then read. This was followed by a talk by Mr. William Maver, Jr., of New York, on "Recent Improvements in Wireless Telegraphy." The discussion of the subject of "Composite Circuits" was then resumed and continued until 1 p. m., when the convention adjourned.

An excellent programme of entertainment was provided for the guests and their wives, including a dinner at the Columbia Club, trolley excursions and a trip to St. Louis over the Big Four Railroad. The courtesies of the free use of telegraph and telephone services were extended to the delegates by the telegraph and telephone companies.

Annual Meeting of the New York Electrical Society.

The annual meeting of the New York Electrical Society was held at the Electrical Testing Laboratories, June 15. The report of the secretary showed that 101 members had been elected during the year; 54 had been dropped for non-payment of dues; 32 had resigned, and 3 had died; and that the total membership is now 631. The report of the treasurer showed that the income of the society for the year ending January 31, 1904, was $1,502.62, and the balance on hand was $34.37.

The revised constitution and by-laws were read for the second time before the society, and after being submitted to the meeting, were unanimously adopted. One essential point in the new constitution is that no officer except the secretary and treasurer shall be eligible for immediate re-election to the same office. The provision for proposed amendments is made much more stringent than formerly. One of the principal features in the amended by-laws is the provision for a nominating committee, which now consists of eight members appointed by the president, with the president ex-officio. Two of these members shall be past presidents, two shall be members of the executive committee, and four shall be non-office holding members, thus giving the largest representation on the committee to the general membership of the society.

The election of officers resulted as follows: President, Frank J. Sprague; vice-presidents, C. G. Young (re-elected), E. H. Mullin (re-elected), F. C. Bates (re-elected), Albert F. Ganz, Louis B. Marks, W. S. Rugg; secretary, George H. Guy (re-elected); treasurer, Henry A. Sinclair (re-elected).

After the business meeting the society was welcomed by Mr. John W. Lieb, Jr., president of the Electrical Testing Laboratories. Mr. Lieb gave a short history of the foundation of the laboratory, which has developed from a lamp testing bureau, founded by the Association of Edison Companies, to its present extensive and complete equipment. Since the laboratory has been opened, all kinds of electrical tests have been conducted, especially on the photometric value of arc lamps, breakdown tests of insulating material, the effect of the distribution of light due to shades and reflectors, meter tests, the standardizing of instruments, the preparation of photometric standards, etc.

Mr. Wilson S. Howell, manager of the laboratories, gave a short address on the "Importance of Testing." He showed that the matter of testing was equally important to the manufacturer and to the purchaser. Among instances given of complete testing equipments, he mentioned those of the Pennsylvania Railroad Company, the Brooklyn Navy Yard, the General Electric and the Westinghouse Companies, and it was demonstrated that the success of all those organizations was due to a great extent to their continuous testing, not only of their own purchases, but also of their own products.

Dr. Clayton H. Sharp addressed the meeting on the "Equipment of the Commercial Testing Laboratory," concluding his address with an exhibition of a number of slides, the most interesting of which were made by a triple oscillograph, showing an alternating e.m.f., and currents set up thereby with an inductance and a capacity in parallel. After an inspection of the equipment of the laboratory had been made a collation was served.

The Largest Rotary Converter.

We are glad to be able to illustrate herewith what is stated to be the largest rotary converter ever built. Although rated at 2,000 kw,

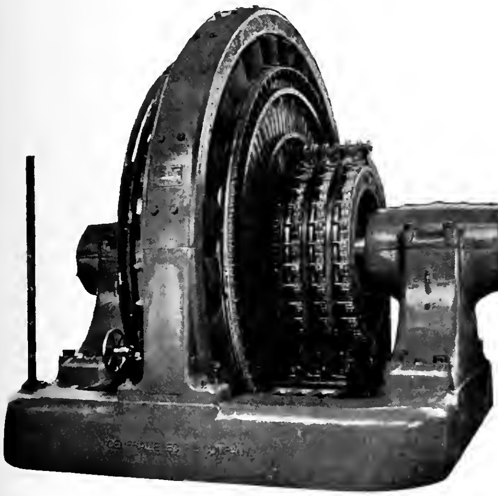

FIG. 1.—ROTARY CONVERTER.

it is actually of greater output, as the specifications call for its delivery of 2,500 kw continuously without any portion heating more than 45° C. It has met all the heating efficiency and overload guarantees with considerable margin. We are indebted to Mr. H. F. T. Erben, of the engineering department, for the data of this machine, whose design, we believe, should be credited to him.

In the nomenclature of the General Electric Company the converter is rated "HC-26-2,000-115-240/300 V.", i. e., it is six-phase, has 26 poles and operates at a speed of 115 r.p.m. Its normal full load is 7,400 amp. at any voltage between 240 and 300. Its armature is nearly 13 ft. in diameter, its commutator 11 ft., and its collector rings are 6 ft. Including the shaft, the revolving parts weigh approximately 35 tons, and the machine complete, with base and two bearings, 93 tons. The overall dimensions are as follows: Height above floor line, 14 ft.; width, 17 ft.; overall length, 15½ ft.

These converters are guaranteed for continuous operation at 7,400 amp. and 270 volts without heating more than 35° C. on any part, and for continuous operation at 9,250 amp. and 270 volts (25 per cent. overload) the temperature rise under this condition not to exceed 45° C. on any part. Immediately following either of the above conditions, 11,100 amp. at 270 volts (50 per cent. overload) for two hours was guaranteed not to produce a temperature rise exceeding 55° C. on any part. The converters have been thoroughly tested

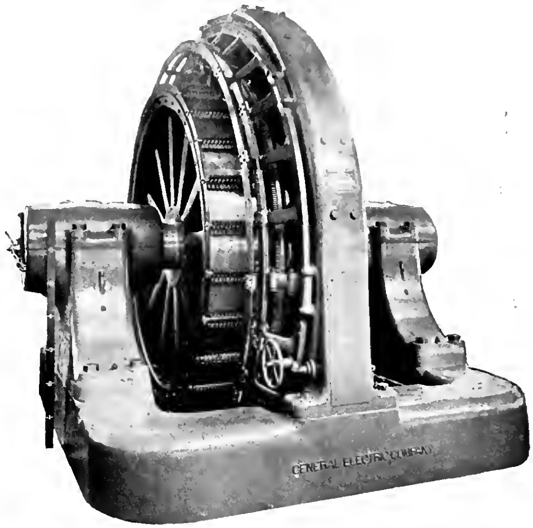

FIG. 2.—ROTARY CONVERTER.

at Schenectady under the normal and overload conditions, meeting the heating guarantees by a liberal margin and commutating throughout the range with practically no sparking at the brushes. Inclusive of all mechanical and electrical losses, the efficiencies were as follows: 1½ load, 95¾; full load, 95¾; ¾ load, 95; ½ load, 93½.

Four of these converters are to be used by the New York Edison Company on its lighting circuits.

45,000 KW Equipment for Niagara Falls Plant.

The Toronto & Niagara Falls Power Company, of which Mr. H. M. Pellat, of Toronto, is president, and Mr. F. S. Pearson, New York, consulting engineer, has just placed a very interesting contract for generators to be installed in its Niagara Falls plant.

There will be six generators of 7,500-kw capacity each. The contract was secured by the Canadian General Electric Company. The contract for the turbines has not yet been determined on.

Mr. W. P. Plummer, 29 Broadway, New York, who is purchasing agent for the Sao Paulo Tramway, Light & Power Company, Brazil, and the Mexican Light & Power Company, Limited, both of which concerns use huge quantities of Yankee equipment, supplies, etc., also acts in a similar capacity for the Toronto & Niagara Falls Power Company.

Allis-Chalmers Turbine Contract.

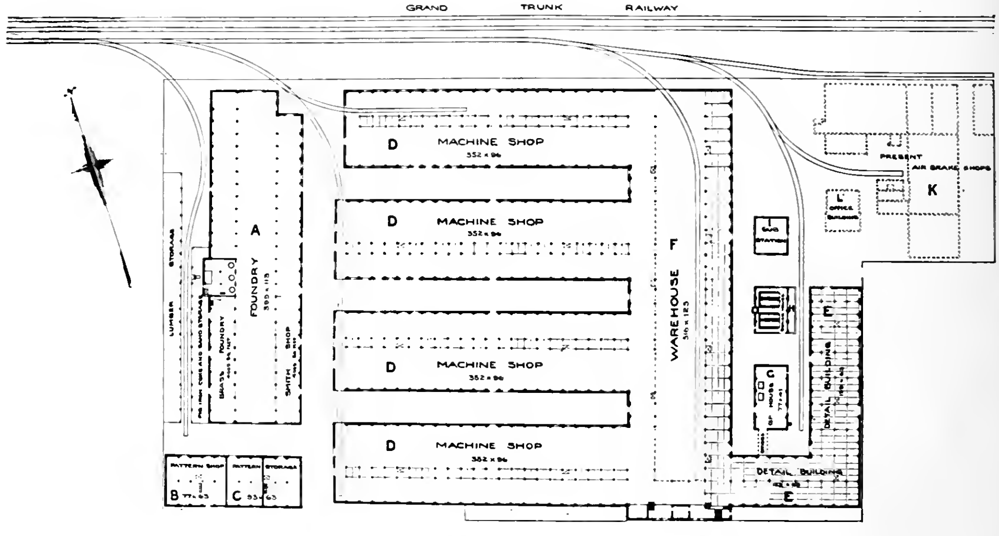
The Transit Development Company, acting on behalf of the Brooklyn Rapid Transit Company, has just placed a contract with the Allis-Chalmers Company for a 5,500-kw turbine to be direct-connected to a 25-cycle, 750-r.p.m., three-phase alternator, wound to give either 6,600 volts or 11,000 volts. This equipment is intended to be installed in the Kent Avenue and Division Avenue power station, Brooklyn. It will be the second generating outfit ordered for the same station, the Westinghouse interests having recently secured a contract for a 5,500-kw turbine and generator. The Kent Avenue plant, it is expected, will ultimately have a capacity of no less than 66,000 kw.

Canadian Works of the Westinghouse Companies.

The accompanying illustration gives a plan view of the new plant of the Canadian Westinghouse Company, Limited, at Hamilton, Ont. The choice for the location of the Canadian plant fell on Hamilton not only from the natural advantages of that city from the manufacturing standpoint, but as well from the fact that for a period of eight years another Westinghouse interest, the Westinghouse Manufacturing Company, Limited, has been located there engaged in the manufacture of Westinghouse air brakes. To join under one management the existing air brake business and the electrical business a new organization was formed under the name of the Canadian Westinghouse Company, Limited. Work on the electrical manufacturing plant has been vigorously pressed from the commencement, and notwithstanding an unusually severe winter, the work was not interrupted, and it is expected that the plant will be in operating condition this fall. The Canadian Company, through an agreement with the Pittsburg Companies, will have the benefit of all designs and processes of the older companies, and aided by the co-operation of many of Canada's most representative citizens the company can confidently count upon a prosperous future.

The new buildings consist of a foundry, pattern shop, pattern storage house, general machine shop, detail machine shop, insulation treating building, boiler house and transformer building. On the electrically driven, receives coke from railroad cars and deposits it in a bin suitably located on the charging floor. The general machine shop is arranged with a high bay covered by a 20-ton crane and a low bay served by a five-ton crane. In the former the heavier machine tools are located and it is here that mainly the stationary parts of generators and motors will be finished. The lower bay will be devoted to the preparation of rotary parts, and the gallery floor above the latter will provide space for the manufacture of commutators, brush holders, bearings, etc., and also for the tool room and the controller department. After the completed rotary part has received its winding in the eastern end of the low bay, it is passed by a jib crane along the mezzanine floor of the high bay, where it is placed in its corresponding stationary part, which has been under construction in this aisle, and the auxiliary parts are delivered at the same point by the elevator from the gallery floor.

In addition to the crane above referred to serving the main portion of the high bay, the eastern end or assembling floor is provided by an additional crane of like span, but of lower level, whereby machines can be delivered from the assembling floor under the west gallery of the warehouse into the middle bay of the latter building, where the north and south cranes can pick up the load for further handling. In the detail machine shop the ground floor will accommodate the coil winding and insulating departments, its loca-



Plan of Canadian Westinghouse Works at Hamilton, Ont.

accompanying diagram these various buildings are lettered from A to L inclusive in the order just given, with the exception that K is the brake plant and L the office building of this plant enlarged to accommodate the increased force of the new company. In laying out the manufacturing buildings two essential points were kept in view, namely, that progress of material from raw to completed shape should as far as possible be in a continuous direction; and that while the initial installation should constitute a complete plant, it should be capable of expansion along its own lines to an extent limited only by the total available property. As to the first point, raw material received on track west of the foundry progresses in general from this point to the warehouse, from which shipments are made over tracks located within the building. As to the second point, something less than half of the total installation shown in the illustration is at present under construction, the northern half of the foundry warehouse and corresponding machine shop buildings being left for future extensions.

In the foundry the main bay is served by a 20-ton crane, the length of the building being also traversed by traveling jib cranes operated at a lower level. An electrically-driven elevator is provided to deliver iron from the yard to the charging floor, and a conveyor, also tion being convenient both for the reception of the wire from the warehouse and delivery of completed coils to the winding and assembling floors at the east end of the general machine shop. The second floor is devoted to machine work necessary on switches, rheostats, meters, instruments, arc lamps, etc., and on the third floor are the assembling and testing rooms for these lines of apparatus.

The insulating treating building is separate from the main group, since the work here involves the use of inflammable materials. Communication with the detail building is provided by a two-story enclosed bridge cut off at each end by fire doors.

Power for manufacturing and testing purposes, as well as for lighting, is to be obtained from a local electric power company, which draws its supply from Decew Falls. Current will be received for general shop purposes. All the lighting distribution will be at 110 volts and transformation to direct current will be made to supply in the transformer house at 2,400 volts and distributed at 440 volts some of the cranes and tools. Transportation between the foundry and all buildings, including the air brake plant, will be by an industrial railway operated by a storage battery locomotive. The construction of the buildings is in the hands of Westinghouse, Church, Kerr & Co., of New York, as engineers and general contractors.

Exhibits at the Railroad Telegraph Superintendents' Convention at Indianapolis.

The J. H. Bunnell Company, of New York, was represented by its president and general manager, Mr. J. J. Ghegan, and Mr. Jesse H. Bunnell. Its exhibit consisted of a line of up-to-date telegraph apparatus; also a new type of star zinc and hanger and a new straight line type of line tapping clamp. Messrs. Ghegan and Bunnell distributed souvenir match boxes.

A Adams-Randall composite circuit set was shown in practical operation. The object of this device is to increase the initial energy of telephone currents to suit conditions and requirements.

Mr. C. K. Jones, of Quincy, Ill., exhibited his automatic telegraph circuit protector and signaling machine, which has received the warm commendation of the officials of the Illinois Central Railroad.

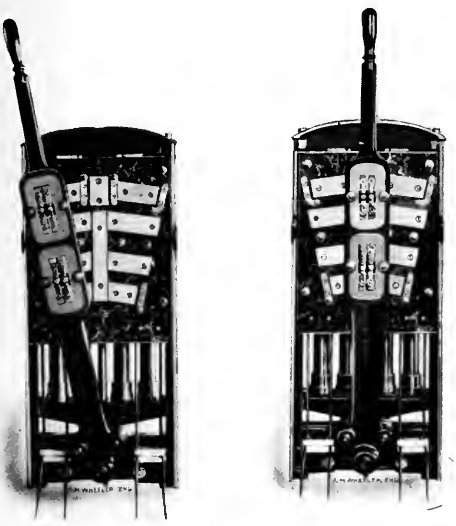
Mr. Vogel represented the Railway Supply Company, of Chicago.

The Safety Insulated Wire & Cable Company, of New York, was represented by Mr. A. P. Eckert.

The Allen-Bradley Electric Crane Controller.

The American Electric Fuse Company, of Chicago, has recently secured the exclusive manufacturing and sale rights to the Allen-Bradley electric controllers, and is now placing this line of apparatus upon the market. An exhibit of these controllers has been installed in the Electricity Building at the World's Fair, St. Louis, where they may be inspected.

While the Allen-Bradley controller is of the carbon resistance type, it differs from other carbon resistance rheostats, both in principle of operation and method of construction. The resistance medium is a column of carbon discs placed inside a non-combustible insulating tube, which in turn is enclosed within an external tube or shield. When an electrical connection is made between the top and bottom carbons, the flow of current through all of the intervening carbons will meet with a very high resistance, due to imperfect contacts between the several carbon discs. To reduce this resistance, a compression lever, operating in connection with springs, is employed to press the discs together, thereby making the contacts between them more perfect. This compression is gradually applied and affords an infinite range of control. When the compression



FIGS. 1 AND 2.—CRANE CONTROLLER.

is released, the carbons, by their natural elasticity, expand to normal condition and the resistance again becomes very great. Any desired resistance may be had by increasing the number of tubes or columns employed in the controller. A simple mechanical adjustment of the operating parts equalizes the compression upon all the tubes in the controller, as indicated in the illustrations, which show a controller having four tubes.

Among the points of superiority claimed for the Allen-Bradley controller are that it has no steps or contact points, and, therefore, the current is not regulated by jerks, while the controller is absolutely free from sparking, welding and arcing. There is no limit to the control of the current flow, and a motor can be driven as fast or as slow as desired, and without danger of injury either to the motor itself or to the controller. The resistance units being entirely enclosed from the air, are not endangered by heat even when the full resistance is left in the circuit for long successive periods of time. The machine is extremely simple in construction and practically indestructible under ordinary use, excepting from external causes. It is specially designed to stand the hardest usage, and to work under the most difficult conditions without breaking down. The controller is very compact, controllers up to 40 hp not exceeding 10 in. in width. It is possible, therefore, to place a much larger number in a smaller place than any other controller. The long leverage of the handle makes it extremely easy to mnnipulate, and the most inexperienced operator cannot injure. No repairs are necessary except when a controller is injured by accident. With ordinary use, an Allen-Bradley controller will last as long as the motor with which it is used.

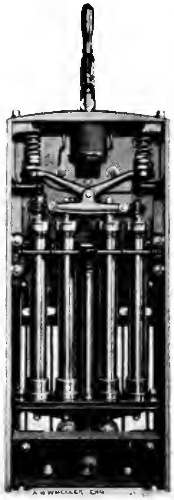


FIG. 3.—CRANE CONTROLLER.

Magnetic Apparatus.

The Electric Controller and Supply Company has designed an interesting line of magnetic apparatus, consisting of lifts, clutches and magnetically operated switches, some types of which we illustrate herewith.

FIG. 1.—LIFTING MAGNET.

Figs. 1 and 2 show lifting magnets in operation. This apparatus is made for the handling of pig iron, ingots, blooms, slabs, billets, bars, plates, rails, structural shapes, iron and steel pipe, and many other raw and manufactured products of iron and steel. A single design of magnet is not adapted to handling the full range of material above mentioned, and the magnet is designed to meet the form of material to be handled. For instance, there is a wide difference in the design of a magnet for lifting ingots or blooms and one adapted to the handling of thin plates. A magnet which would

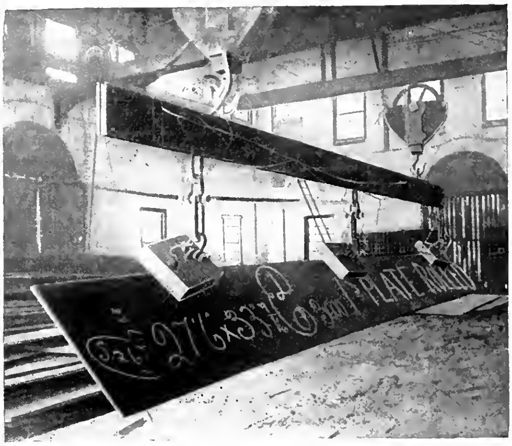

FIG. 2.—LIFTING MAGNET.

handle five tons in the form of an ingot might not handle five hundred pounds in the form of thin plates. The company has secured complete lines of data through the testing of some forty designs of magnets on a testing machine constructed for this special purpose.

In Figs 3 and 4 are shown the "magnetic cushion" type of electromagnet designed to overcome the objections to the employment of the usual type for lifting and other purposes. The initial pull of the magnet through the air gaps encountered in common practice is fully equal to that of a plugged or stopped type of magnet of

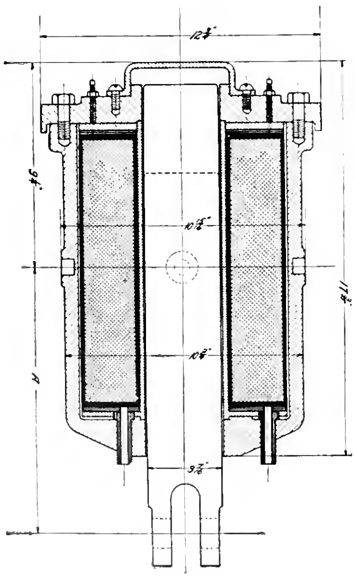

FIG. 3.—CROSS-SECTION VIEW OF ELECTROMAGNET.

equal weight, and a most desirable characteristic is obtained, in that the curve of tractive force is almost a horizontal line, which obviates rapid acceleration of the plunger toward the end of the stroke. The motion of the plunger is arrested simply by the action of the magnetic field, which gives rise to the designation "Magnetic Cushion." No mechanical stop is provided and there is no blow or shock when the plunger is brought to rest at the end of its travel. The magnet plunger, therefore, is silent in operation. For operation in exposed places, the winding of the magnet is completely enclosed

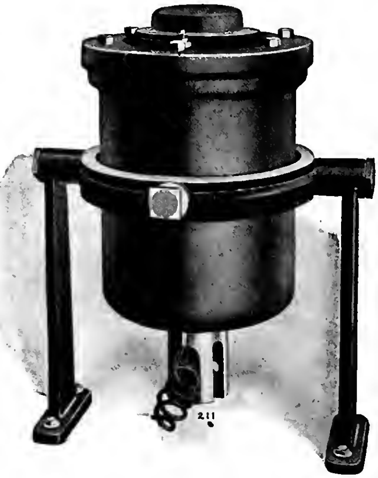

FIG. 4.—GENERAL VIEW OF ELECTROMAGNET.

and protected by the ironclad construction of the return magnetic circuit.

Fig. 5 shows a gravity type of magnetic switch, made in capacities from 1 to 150 amperes. In opening an electric switch circuit carrying a heavy current the switching device employed should meet the following requirements: First, it should open instantaneously; second, its contacts should be protected by a powerful magnetic blow-out, and third, in opening, its contacts should invariably be separated to such an extent that the magnetic blow-out will be instantly effective

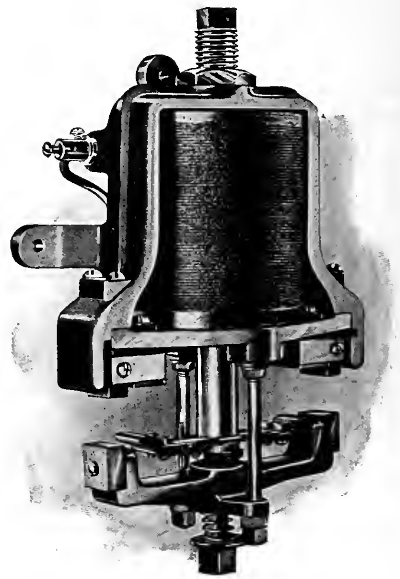

FIG. 5.—GRAVITY MAGNETIC SWITCH.

in rupturing any arc which may be formed. In closing, the switch should act promptly and positively, and the current carrying contacts should be drawn together and held with sufficient pressure to cause intimate contact between their surfaces. The switch illustrated is claimed to possess all of the above characteristics together with other valuable features of its own.

The switch is closed by the direct action of a vertical electromagnet on a movable plunger which carries the contact arm of the switch, and is opened by the action of gravity on the plunger and contact arm, the weight of which is sufficient to produce instantaneous separation of the contacts.

The main contacts of the switch are of copper and are protected by auxiliary contacts of carbon so arranged that the final opening of the circuit always takes place at the carbons, thus protecting the main

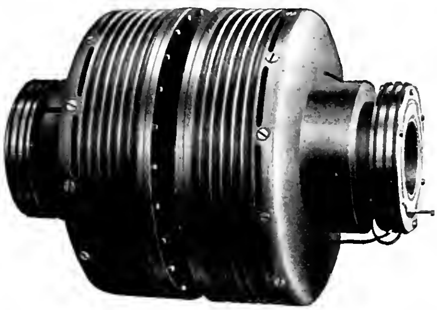

FIG. 6.—MAGNET CLUTCH.

contacts from the effect of arcing of even momentary duration. The construction of the switch is such that the frame of the electromagnet and the arm which carries the movable carbon contacts direct a heavy magnetic flux in the path of any arc which may be formed when the circuit is opened. The pressure between the current-carrying contacts when the switch is closed is produced directly by the pull of the magnet and is therefore positive and constant.

In Fig. 6 is illustrated a large magnet clutch designed for the rapid reversal of a very heavy load, a considerable amount of heat necessarily being generated at the friction surfaces at each reversal. The friction element of this clutch is composed of a plurality of friction plates, keyed alternately to the driving and driven elements and constantly bathed in oil, which serves to lubricate the plates and at the same time transmits the heat to the retaining case, where it is readily dissipated at the corrugated surface of the case.

Electrical Exhibits at the World's Fair, St. Louis.

The handsome booth on the Edison space is divided into three sections, the central one being the headquarters of the American Institute of Electrical Engineers, the one on the right being the office

FIG. 1.—EDISON STORAGE BATTERY EXHIBIT.

of the Association of the Edison Illumination Companies, and the third the office of the Edison historical exhibit. The Edison Storage Battery Company's exhibit occupies an adjoining space. Here are shown three of the latest types of the new Edison battery, one cell of each type having part of the side cut out to show the internal

FIG. 2.—BOOTHS IN EDISON SPACE.

construction. A 40-cell automobile battery is connected to a charging board to show the conditions under variable rate of charge and discharge, and demonstrates the high rates which can be used without effecting the battery. In one show case are the different parts used in the construction of the cells. Plates are exhibited from a cell of an automobile which has run 4,000 miles over rough roads and show practically no deterioration. In another case is shown an historical collection of Edison storage cells beginning with the first cell made and showing one of each type. There are also bottles containing the nickel and iron oxides and graphite used in filling the pockets of the plates. One bottle contains the electrolyte with all the sediment from a cell, which has gone 5,000 miles in an automobile. Only a very thin layer can be seen on the bottom of the bottle. On the wall are some enlarged curves showing battery voltage at various discharge rates. The exhibit also contains ten different types of the Edison-Lelande primary battery and some battery fans operated by them. Several of the Edison projecting kinetoscopes are displayed.

Some of the small motors and generators of the Roth Bros. & Co., Chicago, are adapted to special lines of work. One dynamotor of the transformer type is used by telephone exchanges for ringing bells

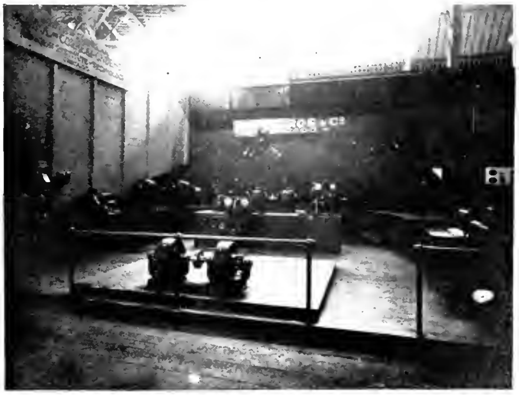

FIG. 3.—ROTH BROS.' EXHIBIT.

with attachments for the "howler," "busy back," "automatic ringing" and "pulsating current" for party lines. Electric grinding and polishing lathes, forge blowers, motor-generator charging sets, motors for 1/16 hp to 15 hp form interesting features of the display. A motor-generator set will furnish light and power for the exhibit.

The Electric Controller & Supply Company is exhibiting in Section 5 an entirely new system of control where the service requires frequent reversals of the driving motor under load. This control has been applied chiefly to the table motors in steel mills where a stop from full speed and acceleration to full speed in the reverse direction of a 50-hp motor under load is required in less than 30 seconds. The adaptation of this system to the operation of planers is shown

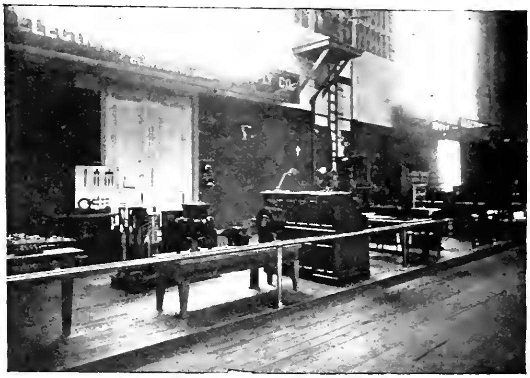

FIG. 4.—EXHIBIT OF ELECTRIC CONTROLLER & SUPPLY COMPANY.

on a 36-in. planer, which is driven through one pinion and gear of a 6-hp variable-speed motor. The motor being direct-connected, is reversed at each end of each stroke of the planer. The motor is compound wound, but the series field is only used for acceleration and is short-circuited when the motor comes to speed. The speed of the cut and return may be varied independently and through a very wide range. This planer is shown in actual operation cutting iron and steel, so that a complete demonstration is given. The advantages claimed for this controller are as follows: It absolutely limits the maximum current which may flow to the motor, thus protecting the motor, gearing and machinery from the effects of abnormal torque; the protection of the motor and machinery does not depend upon the judgment of the operator; the controller protects the motor perfectly in case the voltage of circuit fails. Even if the controller be left in the "full on" position, when the circuit is re-established, the controller will automatically start the motor with the normal amount of current; the operating controller is small and compact, easy of operation and protected from arcing.

A three-ton lifting magnet attached to a hoist is shown lifting steel plates and billets. Magnetic friction brakes and a cushion type

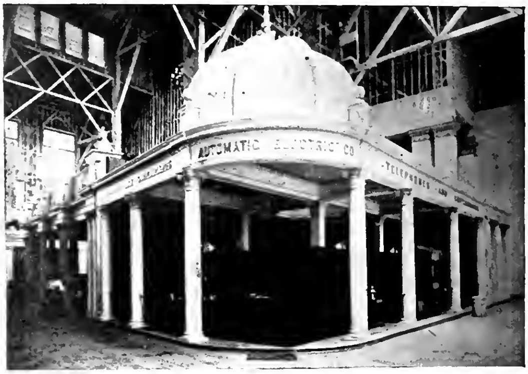

FIG. 5.—BOOTH OF AUTOMATIC ELECTRIC COMPANY.

solenoid are exhibited and in operation. The remainder of the space is filled with a line of controllers for all purposes, crane supplies, resistance units and a magnet for handling pig iron. Another operating exhibit is made by the company in connection with the Niles Tool Company in Machinery Hall, where a 90-hp electric reversing clutch operates a 12-ft. planer. This is the largest planer ever built and its operation by belts would be impossible.

The Automatic Electric Company's exhibit of telephone apparatus is attracting general attention on account of the time and trouble-saving features of the automatic system. This exhibit includes two complete working automatic exchanges of the 10,000 type, each with

FIG. 6.—EXHIBIT OF AUTOMATIC ELECTRIC COMPANY.

100 stations installed. These two exchanges, which are now giving service throughout the Electricity Building, are connected together by a system of trunks, similar to that generally used to connect branch exchanges to each other. The selection of trunks, however, is done automatically. The automatic system requires the use of no name prefixes, and the subscriber need not be aware that he is calling through more than one exchange, since the directory contains only numerical designations. In all cases three or four rota-

tions of the calling dial will secure instantaneous and direct communication with the telephone desired. The telephones exhibited are of three types, the wall, the desk and the pedestal. All of these telephones are fitted with the regulation calling dial, a circular metal piece, on whose periphera are ten finger holes numbered from 1 to 10. This dial is fixed on an axis at its center, and as the finger is placed consecutively in the hole corresponding to the digits of the number desired, and the dial turned once for each digit, electrical impulses are conveyed to the switches at the central office setting them in operation and bringing through them the proper connections.

A tollboard of ten stations is also in service, demonstrating the manner in which toll connections are given to users of automatic telephones. The rest of the apparatus displayed is of the same general character as that which may be seen in connection with any up-to-date telephone exchange, save the "tell-tale" board. This is simply a device for the instantaneous location of trouble, wherever it may arise, and consists of a number of lamps on a slate slab, together with a magneto bell. In case of trouble, this magneto bell rings calling the attention of the attendant, and a lamp glows, by the position of which on the board the location of the trouble can be instantaneously ascertained, and promptly rectified. The photograph shows the artistic booth which is elegantly furnished.

The exhibit of the Holophane Glass Company is one of the most striking in the building and is lighted by over 1,000 incandescent lamps. The booth is in the form of a Grecian temple, fronting on three aisles in Section 25. It has a frontage of 77 ft. on the main aisle and 31 ft. on each side aisle. Over the central doorway electric lights covered with Holophane globes form the word "Lux" in white letters and on each side is suspended a large Holophane 16-in. ball, hanging by three chains. On the door casings are torch brackets surmounted by pillars topped with Holophane globes, containing three colored lamps. These are suitably connected to a Reynolds flasher, so that a beautiful change of colors will occur at different intervals. Between these posts are plate glass cases containing samples of the different kinds of prismatic globes and reflectors manufactured by this company. The entrances from the side aisles are through two Grecian porches, the ceilings of which are studded with electric lights in different colors.

The center room of the interior is divided in two portions, showing two dining-rooms, which will be fitted identically, as far as furnishings and fixtures are concerned, but in one case Holophane globes will be used and in the other ordinary globes, so that a person can see at a glance, by looking at the two rooms, the difference in illumination. On each side of this room there is another apartment, suitably divided to show 12 dark rooms, in which there will be an opportunity to compare the different forms of Holophane globes and Pagoda

FIG. 7.—HOLOPHANE EXHIBIT.

reflectors with other kinds of globes and reflectors. The ceilings and walls are all of paneled oak and in the center of the main room is a $2,000 fireplace. The roof of the building will be used by the company for the entertainment of its guests and its offices. On each side of the main entrance are the two words, "Holophane" and "Pagoda" in 18-in. letters made of Holophane globes and will present an ever varying change in color scheme. First the words will appear in red letters, then in green, then in purple; then in red and green, red and purple, green and purple, and finally in red, green and purple. The exhibit is a joint one between the Holophane Glass Company, the Illuminating Appliance Company and the V. R. Lansingh Company.

A notable feature in the booth of the Heinze Electric Company is an induction coil capable of giving a 40-in. spark. Smaller coils for 30, 20 and 12-in. spark machines are also operating. A new

FIG. 8.—BOOTH OF HEINZE ELECTRIC COMPANY.

form of mechanical interrupter giving a maximum secondary discharge with a minimum primary current is especially adaptable for X-ray apparatus. There are a number of tubes capable of carrying heavy discharges necessary to make instantaneous radiographs, some of which have been taken in a fraction of a second.

In the Court of the Electricity Building, the Missouri Electra Water Purifier Company is exhibiting the Kune process of purifying water by electricity for commercial purposes. The electric purifier has a capacity of 500 gallons of purified water per day, the power consumption being 30 amp. at 15 volts. The apparatus consists of a purifier, generator, switchboard, a precipitating tank and

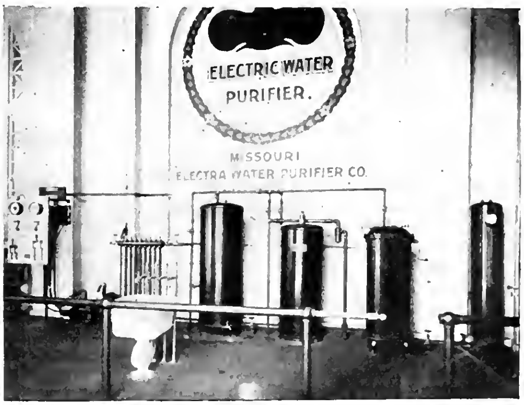

FIG. 9.—MISSOURI ELECTRA WATER PURIFIER.

a filter. The electric current destroys the bacteria and organic matter, also reduces the salts of lime, sodium, magnesium and the like, and any soluble salts of metallic compounds are eliminated. The electrolytic action of the anode produces an insoluble hydrate which acts as a coagulation gathering the released impurities together in an insoluble mass and precipitating them, so that when the water has passed through the strainer or filter, it is free from the impurities. Another interesting feature is a collection of samples of water from the principal cities of the United States, before and after being subjected to this treatment.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—Business on the Stock Exchange was somewhat larger, although it was mainly of a professional character, a few stocks, notably Southern Pacific, constituting the bulk of trading. The favorable character of crop reports had a buoyant effect on the market. The standard stocks seemed to have fair support and there was a more or less buying movement in Manhattan Elevated. The other traction stocks, however, were neglected in spite of continued talk about the improvement in Brooklyn Rapid Transit earnings. On Friday Metropolitan Street Railway and Third Avenue developed exceptional weakness on the report that the Metropolitan Street Railway Company would not pay the first quarterly dividend of 1¼ per cent. on Third Avenue stock, under the terms of the lease of that road. The industrial list was neglected, apart from the firm tone of Steel preferred, which was due to the anxiety of the short interest in the latter owing to the continued intimations that the earnings for the June quarter may be as large as $18,000,000, and that the maintenance of the preferred dividend may be depended upon. In the traction list, Brooklyn Rapid Transit lost ¼ point and Metropolitan Street Railway 2⅜ points on the week's business. The former closed at 48⅛ and the latter at 111½, which was also the lowest quotation of the week. There was considerable trading in Metropolitan, the sales aggregating 50,600 shares. General Electric closed at 152¼, ex-rights, this being a net gain of 1¼ points over the last previous quotation. General Electric rights were sold at 5, which was also the closing figure. Westinghouse was steady throughout the week at 156. Western Union was quiet and unchanged at 87½, while American Telephone & Telegraph closed at the highest point, namely, 129¼, this being a net gain of 1¼ points. The curb market was generally reactionary following the trend of the exchange. There was a further sharp rise in Interborough Rapid Transit stock to a new high record. Following are the closing quotations of June 21:

DIVIDENDS.—The directors of the American Telephone & Telegraph Co. have declared the regular quarterly dividend of 1½ per cent. and an extra dividend of ¾ per cent., payable July 15. Otis Elevator directors have declared the regular quarterly dividend 1½ per cent. on the preferred stock, payable July 15. The directors of Detroit United Railway have declared the regular quarterly dividend of 1 per cent. on the capital stock, payable Aug. 1. New York Air Brake directors have declared the regular quarterly dividend of 2 per cent. The dividend is payable July 15. The Mackay companies have declared a regular quarterly dividend of 1 per cent. on the preferred stock, payable July 9. The Southern New England Telephone Co. has declared a quarterly dividend of 1½ per cent., payable July 16 to stockholders of record June 30. It is expected that the announcement of the terms of the new stock will be given out in July. The International Steam Pump Company has declared the regular quarterly dividends of 1½ per cent. on the preferred and 1 per cent. on the common. The regular quarterly dividend of 1¾ per cent. on Metropolitan Street Railway is payable July 15. The Cincinnati Gas & Electric Company's directors have declared a quarterly dividend of 1⅛ per cent., payable July 1. This is an increase of ⅛ per cent. Union Traction of Indiana directors have declared a dividend of 1 per cent. on the common stock, payable July 1. Directors of the Hall Signal Company have declared the regular quarterly dividend of 1½ per cent. on the common stock, payable July 1.

ROCHESTER (N. Y.) CONSOLIDATION.—The Rochester Railway Gas & Electric merger is regarded as virtually assured. More than 20,000 out of a total 25,000 shares of Rochester Railway common stock has been deposited in assent to the plan, and one of the lighting companies has ratified the agreement. Threatened litigation on the part of a rather large preferred stockholder in one of the latter companies is not expected to interfere with the consummation of the plan. The combining companies are reported to be earning the equivalent of at least 5 per cent on the preferred stock of the new company, the stock being entitled to 4 per cent. per annum the first two years. The receipts for the new common stock, $20 paid, are quoted at about 37 to 39. Rochester Railway common receives 120 per cent. in the new Rochester Railway Gas & Electric preferred.

BROOKLYN RAPID TRANSIT BONDS.—The Brooklyn Rapid Transit has sold $3,000,000 of its 4 per cent. bonds at about 79½. Of the total amount $1,000,000 each was taken by an insurance company and a trust company. The bonds are a part of the authorized issue of $150,000,000, of which only $5,000,000 has been issued so far.

BOSTON TROLLEYS.—The Boston Suburban Electric Companies are issuing new stock at $66.67 per block of one share of preferred and one of common. Stockholders can subscribe at the rate of one block for every four shares held. The issue is to consist of 15,848 additional preferred shares and 15,848 common.

VIRGINIA TROLLEYS.—Richmond (Va.) dispatches state that the Chesapeake Transit Company has applied to the Corporation Commission for authority to increase its capital to $1,500,000 from $1,000,000. The company operates an electric road from Norfolk to Virginia Beach.

THE NIAGARA, LOCKPORT & ONTARIO POWER COMPANY has voted to increase its capital stock from $1,000,000 to $10,000,000 to construct the canal from the Niagara River, under a State charter granted ten years ago.

MANHATTAN FIRE ALARM.—At a special meeting of the stockholders of the Manhattan Fire Alarm Company, held recently, the proposition to increase the capital stock from $500,000 to $700,000 was adopted.

Commercial Intelligence.

THE WEEK IN TRADE.—Conditions have been more favorable, among the features being a further improvement in leading crops and the ending of the tie-up on the lakes. General trade and industry still remain quiet. The notable underlying feature of the entire situation is the feeling that with an average crop of wheat and large yields of other cereals and cotton now in prospect, a good fall and winter business may be looked for. Prices of leading products have felt the influence of crop news, wheat, oats and cotton declining, while corn has remained steady on reports of backward conditions and small supplies offered. Railway earnings reflect current quietness in business, transportation business in general, however, being better than in 1902. Bank clearings show an enlargement over the week previous, but the grand totals are less than those of a year ago. Collections still reflect the influence of a backward spring in retail trade and are complained of as slow at a number of centers. Quietness prevails in the leading industries, iron and steel being dull and production curtailed. Prices, however, are a little firmer. Demand for structural material is inactive. The lumber trade is rather irregular, being much depressed on the Pacific coast, fairly active in the Northwest, but rather dull in the East. Dispatches to *Bradstreet's* from leading centers indicate a moderate business and conservative buying, not in all cases, however, equal to last year. The copper market was lower, weak and uninteresting. Prices are: Lake, 12⅝ @ 12¾; electrolytic, 12⅜ @ 12⅝; casting stock, 12⅛ @ 12¼. The exports continue on a large scale. There were 181 business failures during the week ending June 16, according to *Bradstreet's*, against 171 the week previous and 165 the corresponding week last year.

EXPORTS OF MACHINERY.—An interesting statement has just been issued by the Bureau of Statistics at Washington showing the rapid increase in exports of machine tools and allied apparatus. Exports of agricultural implements from the United States in the fiscal year about to end will amount to about $25,000,000 in value. This is an increase of about $4,000,000 over last year and about $9,000,000 over the preceding year. In no class of manufactures exported has the growth been more steady and persistent than in that of agricultural implements. Comparing the growth in exports of agricultural implements with that in other articles during the same period, it may be said that cars and carriages have increased from $3,333,000 in 1894 to a probable $12,000,000 in 1904; chemicals, from nearly $7,500,000 in 1894 to a probable $14,500,000 in 1904; scientific instruments, from $1,500,000 in 1894 to $8,000,000 in 1904; and manufactures of leather, from $14,000,000 in 1894 to approximately $33,000,000 in 1904, while agricultural implements have increased from $5,000,000 in 1894 to a probable $25,000,000 in 1904. A table prepared by the Department of Commerce and Labor shows that of the $19,000,000 worth of agricultural implements exported from the United States during the 10 months for which detailed figures are available, nearly $10,000,000 went to Europe, $4,000,000 to South America, $3,000,000 to North America, $1,500,000 to Asia and Oceania, and a little over half a million dollars' worth to Africa. The values of the exports of agricultural implements for the years 1897 to 1904, inclusive (May and June of this year being estimated), are as follows: 1897, $5,240,686; 1898, $7,609,632; 1899, $12,432,197; 1900, $16,099,149; 1901, $16,313,434; 1902, $16,286,740; 1903, $21,006,622; 1904, $25,000,000.

ORDERS FOR TELEPHONE APPARATUS.—The Attica Telephone Company, of Attica, Ind., has recently placed with Frank B. Cook, of 239 West Lake Street, Chicago, an order for his type L iron frame distributing rack, to be equipped with his protectors having the self-soldering heat coil. The distributing frame is equipped for 600 pairs, and the telephone company has recently discarded its old protective system. Among the other Indiana exchanges, which have recently been equipped with Cook's apparatus are Worthington (which has the same style of frame with a capacity of 400 pairs), South Bend, Fort Wayne, Bedford, Franklin, Garrett, Brookston, Frankfort and La Fontaine. Mr. Cook has also completed the shipment of a large distributing frame for the automatic exchange of the Home Telephone Company, of Los Angeles, Cal. This is what Mr. Cook styles his "No. 444," with self-soldering heat coils, and the frame is equipped for 4,875 pairs. He previously equipped the manual exchange of the Home Telephone Company with a frame having a capacity of over 10,000 pairs, and using Cook's well-known "No. 4" protectors. Mr. Cook has also recently filled large orders for his protective devices from the Pittsburg & Alleghany Telephone Company, and from the Kellogg Switchboard & Supply Company, for their Louisiana Purchase Exposition exchange. A large order has also been received from Rome, Italy, showing that the apparatus is well known in foreign countries as well as in the United States.

FLOATING INDUSTRIAL EXHIBITION.—The Northwestern Commercial Company, of Seattle, Wash., is to dispatch the S. S. "Victoria" from that city on November 15, to carry a floating industrial exhibition to visit the cities of Yokohama, Kobe, Nagasakai (Port Arthur and Vladivostock, if war conditions permit), Shanghai Hong Kong, Manila, Singapore, Colombo, Mauritius, Delago Bay (Johannesburg and Pretoria), Cape Town, Adelaide, Melbourne, Sydney and Honolulu. The "Victoria" is large, commodious and fast. She was purchased from the Northern Pacific Railroad Company and her first-class passenger accomodations have been renewed at an expense of about $100,000. The vessel has accommodations for 226 first-class passengers, but the number on this exhibition tour will be limited to 100 actual exhibitors, with the opportunity of 50 of them to take their wives, making a total maximum number of 150. The lower decks of the vessel, ordinarily used for second and third-class passengers, will be arranged in the most convenient manner for exhibition purposes. These decks are large and spacious, and will be divided among the exhibitors. They will be decorated and brilliantly lighted by electricity, and while the vessel is in port the exhibition space will be open to the general public from 8 a. m. to 11 p. m. Steam or electric power will be furnished to any exhibitor requiring same. The scheme is not altogether new and will remind some electrical people of the "Great White Special" of a few years ago.

MAY EXPORTS AND IMPORTS.—The statement of imports and exports of merchandise, gold and silver for May and for eleven months ending May is notable as showing that imports of merchandise are, in a measure, stationary, while the exports of merchandise show rather large fluctuations. This fact is borne out by a comparison with May in 1903, the merchandise imports for the month being about $1,000,000 more than in May, 1904, while merchandise exports decreased about $11,000,000. The excess exports of merchandise for May were the smallest since August, 1903, due in a large measure to the falling off in the demand for American wheat and cotton, the exports of which were greatly restricted by high prices prevailing here. For the eleven months ending May the exports of merchandise are the largest on record, with the exception of 1901, and the imports for the eleven months are the largest on record with the exception of the same period in 1903. From present indications the excess exports for the current fiscal year which ends June 30 will be in the neighborhood of $470,000,000, which would compare with $349,372,000 in 1903, $478,398,000 in 1902, and $664,592,000 in 1901.

1,500 MILES OF COPPER CABLE.—The Mexican Light & Power Company, whose New York offices are at 129 Broadway, has placed a contract for copper cable which is claimed to be the largest ever awarded. The contract calls for no less than 1,500 miles of cable, equal in carrying capacity to 3/0 B. &. S. gauge and weighing nearly 2,000 tons. The cable is to be utilized on the power transmission line now under construction by the company between its power plant at Necaxa, which is to have an initial capacity of 45,000 hp and an ultimate development of 80,000 hp, to Mexico City and from there on to El Oro mining district. It will be supported on steel towers in spans of 500 ft. The length of the spans, together with the necessity of reducing the dip as much as possible and the high wind pressure to be withstood make the matter of cables one of considerable importance. The cable was designed by Mr. W. G. Clark, the electrical engineering expert of Seattle, Wash. The Ansonia (Conn.) Brass & Copper Company has been allotted the contract.

EQUIPMENT FOR APARTMENT HOTEL.—A 12-story apartment hotel is to be built at Eighty-ninth Street and Central Park West, New York, which will be installed with an electrical plant. Mr. Peter Banner, of 648 Broadway, is to be the owner; Mr. Robert T. Lyons is the architect. Mr. Percival Robert Moses, 35 Nassau Street, has been retained as consulting engineer. There will be three horizontal return tubular boilers of 150-hp capacity each. The engines will be three simple automatic high speed horizontal type. Two will be 14 in. x 14 in. while one will be a 13 in. x 12 in. They will operate at from 275-300 r.p.m. The generators will be direct current, compound wound multipolar, 240 volts. There will also be an extensive storage battery system.

NERNST LAMP ORDERS.—That the Nernst lamp is rapidly coming into favor in the city of Chicago, is evidenced by the fact that many of the company's customers are placing orders to increase the size of their Nernst lamp installations. Among these are Armour & Co., also Nelson & Morris at the Union Stock Yards. The former company has recently added six 6-glower and nine 3-glower Nernst lamps to its system, while Nelson & Morris have increased their already large installation with twelve 3-glowers. In this connection it may be mentioned that Swift & Co. in the same locality have 125 6-glower and 750 3-glower Nernst lamps in satisfactory operation.

HEINE BOILER ORDERS.—The Heine Safety Boiler Company has secured a contract for a 500-hp outfit to be installed in the additional plant to be constructed by the Quincy (Ill.) Gas & Electric Co. The Edison Illuminating Co., of Pottsville, Pa., is also about to extend its plant, and will put in a 250-hp boiler equipment. Two 250-hp Heine boilers are to be installed in the electric power plant at the new Wabash passenger station at Pittsburg. The Marysville (O.) Water & Light Co. has ordered a 300-hp outfit for its plant.

GENERATORS FOR WAR DEPARTMENT.—The Ridgway Dynamo & Engine Company, Ridgway, Pa., has just been awarded a contract for four 75-kw direct-connected generating sets by the War Department, through the Major of Engineers at Seattle, Wash. These sets are for lighting and power purposes at various Pacific coast army posts and are to be delivered immediately.

G. E. MOTOR EQUIPMENT FOR JAPAN.—Eight hundred G. E. 54 motor equipments will be used in the cars for the Tokio Street Railway Company, which concern is building some 30 miles of electric traction system in Tokio, Japan. The power house equipment will be of 7,000-kw capacity and will be the largest electrical plant in the Far East. Curtis turbines will be installed.

EQUIPMENT FOR NEW OFFICE BUILDING.—Orders are about to be let by the Geo. A. Fuller Company, New York, for the electrical equipment to be installed in the new office building under construction at 78 Wall and 158 Pearl Streets for the Taber Company. There will be two 12-in. x 11-in. engines direct-connected to 50-kw generators.

THE WATERTOWN STEAM ENGINE COMPANY is now installing a 400-hp compound condensing engine in Catskill, N. Y. It has just shipped three engines aggregating 600 hp to Trinidad, Col., and is now building a fourth to develop 1,000 hp arranged for direct connection to a 600-kw General Electric generator.

General News.

THE TELEPHONE.

PHOENIX, ARIZ.—The Phoenix Independent Telephone Company which has just been organized is now soliciting business in this city, and is endeavoring to get 500 subscribers. It is stated that the initial expenditure for installation will be about $50,000.

LOS ANGELES, CAL.—The Pacific Coast Telephone Construction Company, of Los Angeles, has been incorporated with a capital stock of $25,000. The directors are Charles F. Guthridge, Charles L. Zahn, Arthur Wright, and others.

DAHLGREN, ILL.—The Dahlgren People's Telephone Company has increased its capital stock from $5000 to $10,000.

SHELBYVILLE, ILL.—The Duvall Mutual Telephone Company has been incorporated with a capital stock of $420. The directors are C. E. Kreig and others.

SUMMITVILLE, IND.—The Boone Township Telephone Company has incorporated with a capital stock of $1000.

PORTLAND, IND.—The Farmers' Co-operative Telephone Company of Jay County has filed articles of incorporation with the Secretary of State. The capital stock is $15,000. W. H. Harkins, Suphus Straley, E. W. Polly and others are the incorporators.

ST. JOHN, KAN.—The Albany Telephone Company has been incorporated with a capital stock of $840.

BARNARD, KAN.—The Barnard Telephone Company has been incorporated with a capital stock of $5000.

DELPHOS, KAN.—The Rural Telephone Company has been incorporated with a capital stock of $3400.

HOXIE, KAN.—The Sheridan Telephone Company has been incorporated with a capital stock of $2000.

MAHASKA, KAN.—The Mahaska Telephone Association has been incorporated with a capital stock of $3500.

CHAPMAN, KAN.—The Chapman Mutual Telephone Company has been incorporated with a capital stock of $5000.

EUREKA, KAN.—The Greenwood County Telephone Company has been incorporated with a capital stock of $33,000.

LOUISVILLE, KY.—The London and East Bernstadt telephone companies, connecting Clay and Laurel counties, have been consolidated, with a capital stock of $14,000.

BREAUX BRIDGE, LA.—There is a movement on foot in this town to organize an independent telephone company. It is proposed to operate an exchange here and build toll lines to St. Martinville, and other points in the parish.

CASCO, ME.—The Casco Telephone Company has been organized with a capital stock of $10,000. The officers are: President, Richard Cook; treasurer, Herman L. Cook.

WATERTOWN, MINN.—The Watertown Telephone Company has filed articles of incorporation, the capital being $25,000. The officers are: President, F. A. Barth; vice-president, G. F. Peterson; secretary, G. E. Halgren; treasurer, R. J. Burke.

SENECA, MO.—The Seneca Telephone Company has applied to the city for an extension of its franchise for 20 years.

LINCOLN, NEB.—The Western Telephone Company has been incorporated with an authorized capital stock of $1,000,000. The incorporators are Charles J. Bills, Mark Woods, George J. Woods, Frank H. Woods and Thomas H. Ewing. The company intends to construct long-distance lines to make connections with the independent system in Lincoln. One line has been constructed already, the wires running from Lincoln to Havelock, and there connecting with the Plattsmouth Company that has run its wires to this town. Five other long distance lines are projected. One is to Nebraska City; another taps the southeast section of the State and runs generally in the direction of Falls City; a third will run for the business of Saline and Fillmore counties; the fourth will be in the direction of York, and the last will run to Davey, where the Golden Rod system is already installed.

TRENTON, N. J.—The system of the Interstate Telephone Company between this city and Atlantic City has been completed, and direct telephone communication between the two points is now possible. The line goes to Atlantic City by way of Philadelphia.

ALBANY, N. Y.—The extension of the Rensselaer County Telephone Company's system through the city of Rensselaer is one of the future probabilities. Application for a franchise is now being made. The company will have connection with the Home Telephone companies of Albany and Schenectady.

CATSKILL, N. Y.—The telephone war in this village, which was noted last week, has been brought to a close, the West Shore Company agreeing to raise its wires and thus avoid lengthy litigation if it persisted in obstructing the construction of the lines belonging to the Hudson River Company.

ELIZABETH CITY, N. C.—A company has been organized to construct a telephone line from this place to Weeksville, a distance of 16 miles. Contracts for the construction work have been awarded.

MARSHFIELD, ORE.—E. C. Drew and Ed Riggs propose to establish a telephone system here.

WELLSTON, OHIO.—The Wellston Mineral & Athens Telephone Company has increased its capital stock from $2000 to $30,000.

WESTMINSTER, OHIO.—The United Farmers' Telephone Company, of Westminster, has increased its capital stock from $10,000 to $20,000.

CLEVELAND, OHIO.—The United States Telephone Company, it is stated, is about to begin construction work, the wire alone for which will cost $160,000. This work will include the new line between Dayton, O., and Richmond, Ind., which will give long distance connections through Indianapolis and St. Louis to Kansas City. Lines will be strung into Cincinnati and Wheeling, W. Va.

CHARLESTON, S. C.—A commission has been issued to the Coast Line Telephone Company, of Charleston, which will establish a telephone system on the coast islands. The capital stock is placed at $15,000, and the petitioners are: C. B. Jenkins, F. W. Towles and Julian Mitchell, Jr.

HAMMONDSPORT, S. C.—The several rural telephone lines centering in Hammondsport have formed an association known as the Hammondsport Rural Telephone Association. The following officers have been elected: Robert Sherer, president, and Maurice A. Hoyt, manager.

AUSTIN, TEX.—The Bay City & Matagorda Telephone Company, of Bay City, has been incorporated with a capital stock of $5000. The names of the incorporators are W. W. Boulden, R. H. Taylor, of Bay City, and A. W. McNab, of Matagorda.

DENISON, TEX.—The Grayson County Telephone Company will make improvements to its system between Denison and Sherman at a cost of $50,000. Fifty thousand feet of cable will be purchased and the equipment will be renewed and improved wherever necessary.

GALVESTON, TEX.—It is stated that H. E. Huntington has absorbed twenty-three additional independent telephone systems and leased lines in Texas, Arkansas, Indian Territory, Louisiana and Oklahoma, many of them being located in prominent cities, including Galveston, Houston, Dallas, Fort Worth, San Antonio, South McAlester, Little Rock and Oklahoma City, Okla. It is understood that Mr. Huntington and his associates have set aside $10,000,000 with which to organize a rival company to the Southwestern Telephone & Telegraph Company. It is also learned upon good authority that the Southwestern consolidation is but a nucleus with which to initiate a telephone organization that will give local and long-distance service throughout the United States.

EVERETT, WASH.—The Tualco Telephone Company has been incorporated with a capital stock of $1000. The names of the incorporators are F. E. Ferguson, F. E. Phelps and T. W. Bennett.

RACINE, WIS.—The Citizens' Telephone Company has purchased a site in this city on which it will erect a new telephone exchange. The company was organized three years ago and now has 2000 subscribers.

HONOLULU, HAWAII.—A quasi-government system of telephone has just been completed on the island of Molokai and is worked in connection with the wireless telegraph system of the Hawaiian Islands, and through that with the Pacific cable. The system is a sort of communal one, the people themselves agreeing to maintain and keep in repair the portion of the line in their respective districts.

ELECTRIC LIGHT AND POWER.

LUVERNE, ALA.—It is proposed to construct water works and an electric light plant at a cost of $10,000. No engineer has been selected as yet. Bids will be received after July 1. A. B. Brooks is city clerk.

NASHVILLE, ARK.—It was voted June 2 to construct water works and an electric light plant.

OXNARD, CAL.—The Oxnard Light & Power Company is having plans prepared for an electric power house and plant.

NORFOLK, CONN.—J. H. Roraback, of Canaan, is interested in the construction of an electric light plant on Mill River to furnish power to Canaan and Norfolk.

HARTFORD, CONN.—The Hartford Electric Light Company, Hartford, Conn., has bought a tract of land and will erect a power plant to take the place of its present Pearl Street plant. The company's Westinghouse-Parsons turbine will be removed to the new plant, and it is understood that it will install another turbine set of the same type, as well as increase its boiler capacity.

MONTICELLO, FLA.—The electric lighting plant, owned by J. M. Henry, of this town, was destroyed by fire some time ago and has not been rebuilt. The town is greatly in need of a plant and the erection of a new one is now in contemplation.

ALBANY, GA.—It was voted June 9 to issue $10,000 bonds for improvements to the water works and electric light plant.

WOODHULL, ILL.—The Woodhull Electric Light Company proposes installing a new dynamo and will be in the market for the same.

INDIANAPOLIS, IND.—H. C. Hendrickson is preparing plans for a brick power-house for the Martinsville Light & Power Company.

ELKHART, IND.—The Elkhart City Electric Company has been incorporated, with a capital of $50,000. Incorporators: C. G. Conn, P. L. Turner and W. J. Gronert.

OXFORD, IND.—The managers of the municipal electric lighting plant here are figuring on lighting two other small towns at a distance of 5 and 8 miles. Current will be transmitted at a voltage of 6600 to the most distant town and step-up transformers will be required.

BOONE, IA.—It is stated that the Council will take up the matter of an electric light plant for the city at once.

AFTON, IA.—It is proposed to give the municipal electric lighting plant in this place a general and complete overhauling.

LOUISVILLE, KY.—The American Electric Lighting Company, of Oakdale, has filed articles of incorporation, the capital stock being fixed at $10,000. The incorporators are Charles A. Hess, Mary Rosenfield, Louis F. Otto and Thomas Flordon.

BANGOR, ME.—The Underwriters' Light, Heat & Power Company has been organized at Bangor, with $3,000,000 capital stock. E. T. Nealey, of Bangor, is president, and Frank L. Goodwin, treasurer.

BALTIMORE, MD.—Bids will be received by James Knox Taylor, supervising architect, Treasury Department, Washington, D. C., June 27, for the installation of an elevator plant and electric house pumps at the U. S. Post Office, Baltimore.

BOSTON, MASS.—Sealed proposals for boilers, engines, generators, cables and conduit for electric light and power plants will be received at the office of the United States Engineer, in this city, until July 11. Information can be obtained on application to W. S. Stanton, Lieut. Col. of Engineers.

KALAMAZOO, MICH.—The Council has under consideration the matter of issuing $18,000 bonds for improving the electric plant.

ROYALTON, MINN.—Plans and estimates are being prepared for a municipal lighting system, and the matter will be submitted to a vote of the people.

CHISHOLM, MINN.—The Chisholm Light & Power Company has filed articles of incorporation, the capital stock being $20,000. The incorporators are Nils Anderson, of Virginia, Henry A. Liedel and Daniel D. Crowley, of this city. Duluth will be the principal place of business.

BOONEVILLE, MISS.—Business men of this place have organized a company to establish an electric light plant and telephone system. A franchise has been granted and application for a charter for the new company will now be made. Contracts for the building will be let.

HOBOKEN, N. J.—After a lively meeting of the city council a few evenings ago the contract for street lighting was awarded to the United Electric Company at $100 per light per year. A joint committee from the Taxpayers' Association and the Hoboken Innkeepers' Association urged the mayor to withold his signature and veto the contract, asserting that they could produce independent bidders if the bids were readvertised for and guaranteeing to make a much lower bid than $100 per light. As the committee refused to divulge any of the names of these proposed bidders, the mayor announced that he would sign the contract.

NORTH ELBA, N. Y.—The Ausable Valley Light, Heat & Power Company, of North Elba, has been incorporated with a capital stock of $30,000. The directors are Wallace Murray, P. A. Gould, A. K. Botsford, of Saranac Lake.

SAG HARBOR, L. I., N. Y.—A proposal to construct an electric light system and issue bonds in the sum of $24,000 to pay for the same was defeated at a special corporation meeting on June 9. This is the third time that the question has been before the people.

ROCHESTER, N. Y.—Papers were filed in two suits on June 10, to prevent the projected merger of the Rochester Gas & Electric Company, the Rochester Railway Company and the Rochester Light & Power Company. The plaintiffs in each case are minority stockholders in the Rochester Gas & Electric Company. The complainants claim that the proposed merger is unlawful and against public policy. At a meeting of the stockholders of the Rochester Gas & Electric Company the proposition to consolidate with the Rochester Light & Power Company was ratified.

LEXINGTON, N. C.—It was voted June 7 to issue $60,000 bonds for the construction of water works and an electric light plant. J. L. Peacock is City Clerk.

WILSON, N. C.—The Wilson Light & Power Company, of Wilson, has been incorporated, with a capital of $125,000, by J. C. Hales, B. T. Lane, Claudius Aycock, and others.

SALEM, OHIO.—The Salem Light & Power Company has been incorporated with a capital of $10,000, by J. S. Khinefelter, J. G. Wilson, C. M. Wilson, and others.

MASSILLON, OHIO.—Bids will be received July 9 by the Board of Trustees of Massillon State Hospital at the office of F. L. Packard, architect, Columbus, for furnishing and erecting in the power-house at said hospital a 450-hp engine, two 350-hp boilers, one 300-kw generator and a switchboard. Address H. C. Eyman, M. D., secretary.

READING, PA.—A bill calling for a special election to obtain the assent of voters for a $200,000 loan for a municipal electric light plant was defeated in the Select Council.

MAHANOY CITY, PA.—Application has been made by Harrison Ball and John I. Mathias, of Mahanoy City; T. D. Jones, of Hazleton, and others, for a charter for the Economy Light, Heat & Power Company.

CHATTANOOGA, TENN.—The City Council has agreed to issue $1,000,000 bonds for the purpose of constructing an electric light plant to be operated by water power. The plant will be erected and controlled by private parties, who will pay the city 5 per cent. for the use of the capital to be derived from floating the bonds, upon which the city will pay interest. The city reserves the right to purchase the plant at the expiration of 50 years, and during the existence of the contract is given 500 free lights.

SHERMAN, TEX.—The Sherman Gas & Electric Company has been incorporated with a capital of $200,000. J. F. Strickland, Dallas, is one of the incorporators.

EL PASO, TEX.—The Mimbres River Water Company has been incorporated for the purpose of carrying on the business of a water company, and construct electric light and power plants for supplying electric lights and power for domestic and public uses in the city of El Paso and other communities: capital, $2,000,000. The principal place of business is Albuquerque, N. M. Incorporators: Geo. W. Delamater and Jas. S. Delamater, of Pittsburg, Pa.; Allan G. Kennedy, of Santa Fe, N. M. and Edw. L. Medler, of Albuquerque, N. M.

BRANDON, VT.—At the annual meeting of the Neshobe Electric Light Company, which was held here recently the directors elected officers as follows: President, Dr. O. C. Baker; vice-president, Charles Dewey; treasurer, George H. McLeod.

SNOHOMISH, WASH.—The plant of the Cascade Cedar Company was completely destroyed by fire, the loss being $6000. The company has secured temporary equipment pending the rebuilding of the plant.

THE ELECTRIC RAILWAY.

SAN FRANCISCO, CAL.—San Francisco and San Jose capitalists have been granted a franchise by Secretary of the Interior Hitchcock to build an electric railway into the Yosemite National Park. This is the first franchise ever granted by the Government for an electric railway into any Government reservation. Stations are to be constructed every 10 miles.

AUGUSTA, GA.—The stockholders of the Augusta & Elberton Railroad have authorized an issue of first mortgage gold 6 per cent. bonds, $10,000 per mile, or a total issue of $750,000. Fred T. Lockhart, secretary and treasurer of the company, says the construction of the line will now soon begin.

MONTPELIER, IND.—The Portland, Montpelier, Warren & Huntington Traction Company has organized by electing the following-named officers: James West, president and general manager; Scott Mills, vice-president; D. A. Williamson, secretary; Levi Huffman, treasurer; George Champe, of Toledo, chief engineer. The final survey of the road will be begun at once, and several agents will be put to work buying the right of way preparatory to immediate construction.

INDIANAPOLIS, IND.—The annual meeting of the stockholders of the Indianapolis Traction & Terminal Company was held here Wednesday, June 8. The only change was that in the election of John J. Appel to succeed James M. Jones as second vice-president of the company. Mr. Jones resigned recently. His place as assistant general manager was not filled. The officers are Hugh J. McGowan, president; H. P. Wasson, first vice-president; John J. Appel, second vice-president, and W. F. Millholland, secretary and treasurer.

SIGOURNEY, IA.—Twenty-five hundred dollars has been raised and a board of directors selected for a company which proposes to construct an electric interurban railway from Sigourney to Newton. The board of directors is as follows: C. B. Holmes, of Chicago, president: H. G. Brown, Thomas Kelly, J. W. Lesan, and others.

PADUCAH, KY.—Word is received here of the financing in New York of the Kentucky & Ohio River Electric Railway, which plans to build from Paducah to East Cairo, Ky.; thence possibly across the river to Cairo, Ill. J. J. Freundlich, of Paducah, and W. H. Paul, of East St. Louis, are interested.

GULFPORT, MISS.—Col. J. T. Jones, of this place, who is interested in the electric railway now under construction here, says the line will most likely be built to Biloxi, Mississisippi City and Pass Christian. Financial interests recently looked into such a proposition, and are said to be willing to put up the money.

WILLIAMSTOWN, MASS.—The Hoosac Valley Street Railway Company has completed the plans for the new line from the Williamstown station to the Vermont line.

ST. PAUL, MINN.—It is reported that St. Paul men, among whom is President A. B. Stickney, of the Chicago Great Western road, are considering a proposition to build an electric railway in Minnesota, to run south from St. Paul to Rochester, linking a number of small towns.

SYRACUSE, N. Y.—The Syracuse Rapid Transit Railway Company plans the construction of another belt in the West End. A franchise application has been presented to the Council asking for permission to lay tracks in seven streets.

PATCHOGUE, N. Y.—The South Shore Traction Company is soon to apply to the Railroad Commissioners for permission to build its line. The line will extend from the New York line at Central Avenue, Jamaica, to the Connecticut River at Brookhaven, a distance of 60 miles, a considerable portion of which will be over private right of way. The following are directors for the first year: R. Lee Slingluff, A. C. Hume, James A. Hawes, S. H. Thompson, F. D. Shaffer, Samuel Worthington, Edward Phillips, Charles Hall Davis, C. G. Perrott. James F. Heyward, formerly connected with the electric railways of Baltimore, is interested in the company as a stockholder.

STEUBENVILLE, OHIO.—The Steubenville & Canton Railway Company has been incorporated, with a capital stock of $10,000, to build an electric railway from Steubenville to Canton, there to connect with the electric railway to Cleveland. The incorporators are Howard H. Smith, Elmer E. Francy, Thomas H. Loomis, Sheridan B. Pyle, James Carl Bibber.

CINCINNATI, OHIO.—The owners of the Cincinnati Interurban Railway Company, operating between Cincinnati and Hamilton, are planning extensive improvements to the portion of the road south of Carthage, in order to make it possible to run the large interurban cars into Cincinnati without change.

POTTSTOWN, PA.—After a fight to enter the borough, lasting over a year, the Pottstown & Reading Street Railway Company has finally been granted a franchise by the Council.

JERSEY SHORE, PA.—The newly chartered Jersey Shore-Antesfort Railway Company has secured a site in this place for a power house. The capital stock is $30,000 and the steam road act, under which the company is chartered, gives it the right to carry freight.

BRADFORD, PA.—A special meeting of stockholders of the Bradford Electric Street Railway Company, and the Olean, Rock City & Bradford Railway Company, will be held in this city July 29 for the purpose of voting on an increase of the companies' indebtedness.

WAYNESBORO, PA.—Surveys have been completed to Pen-Mar of the proposed Catoctin & Meyersville Electric Railway. Connections will be made at Pen-Mar with the Chambersburg, Newcastle & Waynesboro line. The line as surveyed for the Catoctin & Meyersville road runs from the Frederick-Middletown line at Myersville, to Pen-Mar Station, Western Maryland Railroad, a distance of 22 miles. The incorporators of the new road have elected the following officers: J. H. Maugans, president; A. H. Hauver, vice-president; H. M. Warrenfeltz, secretary; Chas. U. Grossnickle, treasurer.

HOUSTON, TEX.—Surveys are now being made for the proposed electric railway between Houston and Galveston. Col. Slosson, of Houston, is the chief promoter.

New Industrial Companies.

THE DOSSERT ELECTRICAL APPLIANCE COMPANY, of New York, has been incorporated with a capital stock of $5000. The directors are: W. F. Blake, Sound Beach, Conn.; James C. Minehan, Albany, and J. E. Calder, New York.

THE DAVID ELECTRIC LIGHT COMPANY, of Alton, Ill., has been incorporated with a capital stock of $2000. The company will conduct a business of electrical construction. The incorporators are: C. B. Davis, B. C. Davis and C. E. Whitney.

THE AUTOMATIC ELECTRIC PUMP COMPANY, of Davenport, Ia., has been incorporated with a capital stock of $30,000. The officers of the company are: President and treasurer, Henry Brehmer; vice-president, William J. Pugh, and secretary, F. J. Peto.

Legal.

RESPONSIBILITY FOR ACCIDENT.—In the suit of Wendler vs. the Red Wing Gas & Electric Company, the Supreme Court of Minnesota has held: 1. The doctrine that the master is not in law bound to instruct an employe as to special dangers incident to the employment if such information is fully within his knowledge, reaffirmed. 2. Certain evidence adduced at the trial fails to show prima facie that an injury was inflicted upon appellant by the negligence of respondent in failing to furnish and maintain proper electrical appliances in conducting its electric light plant, or from failing to keep the same in a safe condition.

BELL WESTERN-UNION ROYALTIES.—Special Master Everett W. Burdett has started hearings in the American Bell Telephone-Western Union Telegraph Company royalty suit, in accordance with the degree of Judge Colt, of the United States Circuit Court, as of Feb. 3, 1904, ordering the American Bell Telephone Company to furnish an accounting to determine to what extent it is obliged to the Western Union Telegraph Company for failure to turn over for 17 years 20 per cent. of stock and dividends it received from sub-companies, in addition to 20 per cent. of the cash rentals. The rental and royalty contract was made between these companies in November, 1879. The amount involved is between $2,000,000 and $4,000,000. In return for these royalties and rentals the Western Union agreed to go out of the telephone business, and turned over all its telephone property to the Bell Company, the latter also agreeing not to interfere with the telegraph business.

GRANT OF RIGHTS IN STREETS.—The Supreme Court of Nebraska in the appeal by the Nebraska Telephone Company to prevent the city of Fremont from destroying its poles and wires, has sustained the lower court and has ruled: 1. When a city ordinance prescribes that permission to occupy the streets by a public service corporation shall be obtained with the consent of the mayor and council, such consent is sufficiently proved by an entry in the records of a meeting of the council, presided over by the mayor, reciting that a motion granting it was offered by a member and adopted; there being nothing to indicate that the mayor dissented. 2. Forfeiture of the franchises and easements of a public service corporation in the streets can be declared and enforced only by a court of competent jurisdiction. The city claiming a forfeiture cannot be a judge in its own cause, or invade the privileges or destroy the property of such a corporation in the absence of judicial warrant for so doing.

CHARGES AGAINST PATENT OFFICE.—In the matter of the charges of Thomas A. Edison against two examiners in the Patent Office, in connection with the grant of letters-patent for an electrical invention by Ernest W. Jungner, the Secretary of the Interior has approved an opinion rendered by Assistant Attorney General Campbell. The opinion holds that nothing is shown in Mr. Edison's petition that involves any cause for the exercise of supervisory authority at the hands of the Secretary, and for that reason the Secretary is advised that the Commissioner of Patents should be left to his own discretion in dealing with the case. The transfer of the examiners from one division to another is recommended by Acting Commissioner Moore, of the Patent Office. Mr. Edison charged "incompetence, neglect of duty and maladministration of office in connection with the grant of a United States patent to Ernest W. Jungner for reversible galvanic battery, No. 738,110, dated September 1, 1903." The findings of Acting Commissioner Moore were that there was absolutely no evidence of malfeasance or intentional wrongdoing on the part of the examiners.

INJURY THROUGH NEGLIGENCE.—In the appeal of Baries vs. Louisville Electric Light Co., for personal injury, the Court of Appeals of Kentucky has reversed the verdict of the lower court for the defendant on various grounds as follows: 1. Under Code Civ. Prac. § 341, providing that a new trial shall not be granted on account of the smallness of the damage in an action for an injury to the person or reputation, nor in any other action in which the damages equal the actual pecuniary injury sustained, a verdict and judgment for one cent for personal injuries resulting in loss of time worth about $800 may be reversed. 2. Plaintiff in a personal injury action alleged that he had been and was unable to do any kind of work. The evidence showed that the time lost by him in consequence of his injury would equal more than $800. The jury gave him a verdict of one cent. Held that, as he had not pleaded special damages, he was not entitled to a reversal. 3. A verdict of one cent for a personal injury consisting of a withered arm, from which plaintiff appeals, will be treated by the Court of Appeals, in considering the errors alleged, as one for appellee. 4. An electric light company, whose failure to properly insulate its wire on a building results in injury to a house painter at work thereon, is not relieved from the consequences of its negligence because the painter's employer knew that the company desired to cut the wire when that portion of the building was to be painted, or because there was a custom that contractors should notify the company when working on houses to which its wires were attached so they could be cut, though the company received no notice in this instance. 5. Where an electric light company had actual notice that house painters were at work on a building to which its wires were attached, evidence of a custom to give it notice of the fact so the wires could be cut is inadmissible in an action by a painter for injury from a defectively insulated wire. 6. The improper admission of evidence in a house painter's action against an electric light company for injuries from a defectively insulated wire on the building he was painting, that a custom existed to notify the company that painters were at work so its wires could be cut, is ground for reversal.

Personal.

MR. C. T. YERKES has sailed again for England to watch his London underground electric railway enterprises.

MR. JOHN A. HEANY has been awarded the John Scott medal of the Franklin Institute, for his magnetic-clutch arc lamp.

MR. H. BEVIS, director of the General Electric Company, Ltd., of London, is again in this country on one of his frequent trips.

MR. J. M. ANDERSON, of the Albert & J. M. Anderson Manufacturing Company, Boston, Mass., was in New York this week.

MR. JOHN G. EMERY, manager of the Shaw Electric Crane Company, Muskegon, Mich., was on a visit to New York for a few days last week.

MR. J. F. FAIRMAN, author of "Telephone Wiring," now in press, has accepted a position with Waterbury & Company, New York City, in their electrical sales department.

MR. ERNST J. BERG, of the General Electric Company, was married week before last to the daughter of Hon. Morgan J. O'Brien, Justice of the New York State Court of Appeals.

MR. F. P. THORP, who has been representing the Power & Mining Machinery Company at Boston, Mass., is now in charge of the Pittsburg offices of that company located in the Farmers' Bank Building.

MR. F. W. PARDEE, who for some time had charge of the telephone department of the Chicago Writing Machine Company, has accepted the position of general manager with Frank B. Cook, of that city.

PROF. W. HALLOCK is to lecture on the influence of radium and other radio-active substances on ionization and the conduction of electricity in gases, with illustrations, during the fifth summer session of Columbia University, which will begin July 6.

MR. H. D. WALBRIDGE has been elected president of the Rochester, N. Y., Gas & Electric Company in the place of Mr. G. W. Archer, and will have associated with him in the management, it is said, Mr. W. M. Eaton, formerly general manager of the Grand Rapids Gas Light Company.

MR. FRANK B. COOK returned recently from a trip to the Black Hills, where he had been looking after his interests in the Deadwood Home Telephone Company, which he owns. He reports the company in a flourishing condition. Mr. Cook returned by way of Omaha, Council Bluffs and Des Moines.

MR. FRANCK Z. MAGUIRE made a demonstration before the Royal Society last year of the Cinematograph in application to travel, engineering, plant growth, cloud effects, etc., and has just issued in pamphlet form his remarks directing attention to interesting features of this work, and its possibilities.

MR. E. B. SWINDEN, of the Montevideo firm of Swinden & Acosta y Lara, which concern is a considerable handler of Yankee electrical supplies, machine tools, etc., is now on a short visit to the United States. He may be reached by addressing the New York banking house of H. B. Hollins & Co., 15 Wall Street.

MR. H. J. M. ELLIS, of H. J. M. Ellis & Company, New York, is now on a visit from Singapore for the purpose primarily of making arrangements with American manufacturers of electrical equipment, supplies, machine tools, etc., to represent their interests in the East Indies. Mr. Ellis intends to sail for Singapore on July 2.

MR. GEORGE E. WILLARD, of the Syndicate of American Manufacturers, 24 South William Street, which concern conducts a considerable business in electrical equipment, supplies, etc., for the South American markets, is about to leave on a trip to the Argentine Republic and the west coast of South America. He expects to be absent fully six months.

MR. R. CRAWFORD has been promoted from superintendent to general manager of the Stamford, Conn., Gas & Electric Company, and Mr. G. B. Leland has been appointed superintendent in his place. Mr. Crawford is also devoting time to the Oven Equipment & Manufacturing Company, a new concern which is making a specialty of gas burners for enameling ovens and core ovens; also for all special heating work.

MR. GUSTAF L. OBERG, secretary and general manager of the Shanghai, China, Mutual Telephone Company, is spending several weeks in the United States on his way to a short visit to his former home in Sweden. The Shanghai exchange has grown so rapidly that plans have been prepared for a large new building which will be equipped with new exchange apparatus, including a 30,000-station switchboard. During his stay in this country Mr. Oberg has visited some of the most recent exchanges, and it is quite probable that the equipment for the new exchange will be purchased in this country.

MR. G. MARCONI made but a short stay here and has sailed again for Europe. Before leaving he stated that the Cape Cod station would be opened very soon for the receipt of wireless messages for the Cunard Line steamers from Boston, as well as the other steamships of the trans-Atlantic fleet. During his return voyage Mr. Marconi will equip the *Kaiser Wilhelm* with his new receiving apparatus. Discussing the reported intent of the United States Government to control wireless telegraphy in the United States, Mr. Marconi said he felt no uneasiness or apprehension as to such action and expressed the opinion that no attempt would ever be made to carry out the reported plan.

Trade Notes.

COLUMBIA LAMPS are the subject of some very pretty and tasteful "dgers" and folders issued by the Columbia Incandescent Lamp Company, of St. Louis.

THE EMPIRE ELECTRIC SUPPLY COMPANY, of Chicago, reports a large demand for Yost sockets, of which it carries a large and complete stock for prompt delivery.

BULLOCK BULLETIN.—Bulletin No. 1020 of the Bullock Electric Mfg. Company is devoted to multipolar motors and generators. The first section of the book illustrates the various parts in complete detail, and the latter part gives a number of engravings of plants that have been installed.

THE TETER-HEANY DEVELOPING COMPANY, York, Pa., has opened business in manufacturing wire insulated with its fireproof insulation. Its product has already met with widespread approval and success, and in consequence of the demand it has begun to enlarge its plant at York.

MR. HORACE F. RUGGLES, 106 Wall Street, New York City, has secured a large Cuban contract for sugar machinery which will be electrically operated. He is figuring on a substantial contract for a sugar plant to be installed in Porto Rico, in which electrical machinery will play an important part.

NERNST LAMP COMPANY.—The Chicago office of the Nernst Lamp Company, in charge of A. E. Fleming as district manager, has been removed from 638 National Life Building, La Salle Street, to 99 E. Lake Street. The new offices are larger and better equipped in every way to care for the increasing business of the company in that locality.

TELEPHONE SUPPLIES.—Bulletin No. 12 of the Empire Electrical Supply Company, 55 W. Jackson Boulevard, Chicago, illustrates a large number of telephone instruments and small types of switchboards. Particular stress is laid upon the "Empire No. 15" receiver, which is claimed to be the most efficient, sensitive, serviceable receiver made.

B. F. STURTEVANT COMPANY announces the removal of its entire plant from Jamaica Plain to Hyde Park, Mass. The new plant has nine acres of floor space and is equipped throughout with the most modern appliances for the manufacture of the well-known Sturtevant products: blowers, engines, motors, economizers, forges, steam heating, ventilating and drying apparatus, etc.

NORTHERN ELECTRICAL MFG. COMPANY, of Madison, Wis., has issued a very neat little leaflet or folder devoted to sawmill practice. One picture in it shows an Italian sawmill of the primitive type—two men sweating over a beam with a hand saw, and two other pictures show a northern spherical motor driving a swing cut-off saw and a Fay buzz saw. The contrast makes a good resetting of an old saw.

LAMBERT SCHMIDT TELEPHONE MFG. COMPANY, of Weehawken, N. J., shows in its catalogue No. 11 on interior telephones an interesting variety of apparatus for private and intercommunicating telephone purposes. All its telephones for this work are equipped with special long-distance cartridge type transmitted and double-pole receiver, and work on its patented central energy circuit, which requires but one bank of batteries.

AN INCANDESCENT LAMP that can stand up under the jolts and jars and hard knocks of street car service is a rare article and few are the factories that can produce it. The Electric Appliance Company, of Chicago, however, claims to have a lamp fitted for this strenuous service and as proof of its statement the company points with pride to the many large traction companies throughout the country which have adopted the Packard railway lamp.

PELTON WATER WHEELS.—The Pelton Water Wheel Company, San Francisco, informs us that it was awarded the contract for the water wheels for the North Mountain Power Company of that city. The statement in our issue of June 11 that the contract had been given for Stillwell-Bierce wheels was an error. The Pelton Company will furnish two double wheel Pelton units, for direct connection to 750-kw, 500 r.p.m., alternators, the wheels to operate under a 600-foot head.

THE F. BISSELL COMPANY, Toledo, Ohio, has added to its list of specialties, novelty potheads, sleeves, terminal heads, etc., for telephone cable work. This business has been purchased outright from the New Haven Company, the transfer including all patents, special machinery, good will and merchandise, finished and unfinished. The Bissell Company announces that, owing to its very advantageous location and special additional facilities, it will be in much better position to serve the trade promptly and satisfactorily.

GARTON LIGHTNING ARRESTERS are the theme of catalogue No. 40, recently issued by the Garton-Daniels Company, of Keokuk, Ia. A large part of this handsome pamphlet is devoted to a discussion of the principles of the subject and the successful manner in which the company's system has been worked out as a preventive and cure of lighting and other "strikes" of a high voltage character. The Garton arrester and its application are clearly illustrated, as well as kicking coils and other details. It is a most interesting summary of the subject.

"NORBITT" TEMPORARY SOCKETS.—At the Elks' convention, to be held in Cincinnati, July 8 to 25, there will be used nearly 30,000 "Norbitt" porcelain temporary sockets for decorative purposes, illuminating the streets for thirty-seven blocks. Oven 500 "Norbitt" temporary sockets will also be used in making a huge American flag, which is to be hung over Government Square. These handy little devices, which can be installed in a very few moments without scraping the insulation from the wire, are manufactured by the Crouse-Hinds Company, of Syracuse, N. Y.

ABNER DOBLE COMPANY, of San Francisco, engineers, manufactu- of tangential water wheels with needle regulating nozzles, dealers and - facturers in iron, steel and metals, announce the organization of its c engineering department, in charge of Mr. Robert McF. Doble, who has siderable experience in the design, construction and operation of hydro-electric power plants and long distance power transmissi Doble Company is now prepared to take entire charge of the de struction of power plants, pumping plants and other engineer

UNIVERSAL ELECTRIC COMPANY.—A new organizat Universal Electric Company, jobbers in everything elect. general sales offices in the Ellsworth Building, 353 Dearborn Street, Ill. Its executive officers are F. C. Royal, president, and F. B. Kavanaugh, secretary and treasurer. Mr. Royal is a well-known Chicago business man, having been connected with the Nelson & Morris packing house for a number of years, while Mr. Kavanaugh was formerly with the Sterling Electrical Mfg. Company, Warren, Ohio, and late with the Brilliant Electric Company, Cleveland, Ohio. The new company is the Northwestern distributer for the Brilliant Electric Company, of Cleveland, Ohio, makers of the Universal tipless incandescent lamps. In addition to this product it will job a full line of arc lamps, fans, motors, generators, telephone systems, etc., as well as several special lamp accessories.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED JUNE 14, 1904.

[Conducted by Rosenbaum & Stockbridge, Patent Attys., 140 Nassau St., N. Y.]

762,279. TELEPHONE LAMP-JACK; Henry P. Clausen, Chicago, Ill. App. filed Oct. 12, 1901. (See page 1198.)

762,297. THIRD RAIL INSULATOR; Henry L. Fritze, Jersey City, N. J. App. filed Oct. 27, 1903. Details.

762,318. CONDUCTOR AND COLLECTOR FOR ELECTRIC RAILWAYS OR TRAMWAYS; Donald Kempt, Buenos Ayres, Argentina. App. filed March 11, 1903. A number of sharp-edged disks run in the groove of a third rail to take off the current.

762,319. CONTACT BOX AND CONDUCTOR FOR ELECTRIC RAILWAYS OR TRAMWAYS; Donald Kempt, Buenos Ayres, Argentina. App. filed Sept. 23, 1903. Details.

762,331. ELECTRIC SIGNAL; Wm. D. Marks, Westport, N. Y. App. filed March 12, 1903. Details of a block signal system.

762,336. SIGNALING APPARATUS FOR TELEPHONE-SWITCHBOARDS; Frank R. McBerty, Evanston, and James L. McQuarrie, Chicago, Ill. App. filed Feb. 20, 1902. (See page 1198.)

762,337. SIGNAL FOR TELEPHONE SWITCHBOARDS; Frank R. McBerty, Evanston, and James L. McQuarrie, Chicago, Ill. App. filed July 2, 1902. (See page 1198.)

762,338. RELAY; Frank R. McBerty, Evanston, Ill. App. filed Oct. 27, 1902. (See page 1198.)

762,341. EARTH OR GROUND WIRE ATTACHMENT; Joseph J. O'Connel, Chicago, Ill. App. filed March 10, 1904. A spring bracket is bound to a water or gas pipe by turns of the conductor to be grounded and extra tension or strain is put upon the turns to perfect the contact by a screw working through the bracket and against the pipe.

762,358. ELECTRIC METER; William Stanley, Great Barrington, Mass. App. filed Dec. 6, 1901. While an oscillating needle is approaching the medial line of its oscillation, the magnetic field is increased independently of variations in the load which determines the normal working field.

762,364. TELEPHONE-CALL INSTRUMENT; Edward W. E. Tompson, Brookline, Mass. App. filed May 18, 1903. (See page 1198.)

762,370. ELECTRIC SIGNALING SYSTEM; Samuel M. Young, New York, N. Y. App. filed Jan. 19, 1903. A system in which the cars are moved by direct current and the signals by an alternating current, the latter being transmitted along the conductors conveying the direct current and interference being avoided by the use of properly disposed reactance coils.

762,379. TROLLEY WHEEL; John S. Briggs, Los Angeles, Cal. App. filed April 25, 1903. In the tread of the wheel, a spring is wound to give yielding contact with the wire to avoid arcing.

762,391. TELEPHONE FIRE-ALARM SYSTEM; William L. Denio, Rochester, N. Y. App. filed May 11, 1903. (See page 1198.)

762,409. SYSTEM OF MOTOR CONTROL; George H. Hill, Glenridge, N. J. App. filed Nov. 3, 1903. A motor control system in which the power-actuated switches are automatically operated in succession and in which the progression may be stopped at any desired point; a master controller is used and the motorman can operate at any speed he desires independently of the automatic progression.

762,410. SAFETY APPARATUS FOR USE WITH OVERHEAD ELECTRIC CONDUCTORS; Herbert F. Hill, London, England. App. filed June 10, 1903. A grounding wire is supported adjacent to a trolley wire and the latter carries brackets arranged to come in contact with the grounding wire in case the trolley wire unduly sags or breaks.

762,425. ELECTRICAL BATTERY; John Roger Lord, San Francisco, Cal. App. filed June 5, 1903. (See page 1198.)

762,430. ELECTROMAGNETIC SIGNAL; Frank R. McBerty, Evanston, and Frederick H. Loveridge, Chicago, Ill. App. filed May 9, 1902. (See page 1198.)

762,432. SUPERVISORY SIGNAL FOR TELEPHONE SWITCHBOARDS; James L. McQuarrie, Chicago, Ill. App. filed May 9, 1902. (See page 1198.)

762,503. ELECTRIC ARC LAMP; Gesa Szuk and Wenzel Hackl, Budapest, Austria-Hungary. App. filed June 3, 1903. Details.

762,535. ELECTRIC PLUG OR SOCKET EXTENSION; Wm. H. Kelsey, Cambridge, Mass. App. filed Oct. 9, 1902. A block of insulating material having a plurality of openings therein containing the parts of lamp sockets or receptacles whereby a number of lamps may be connected with a single plug.

762,571. SWITCH PLATE; John Alexander, Hartford, Conn. App. filed Oct. 29, 1903. The plate is cheaply made by electro-depositing a hard metal face upon a cheap metal body.

762,620. PUMP CONTROLLER SYSTEM; Authur C. Eastwood, Cleveland, Ohio. App. filed Feb. 13, 1903. A magnetic clutch is placed between the motor and the pump, so that the motor may be run continuously and the pump connected when necessary.

762,621. MAGNETICALLY OPERATED SWITCH; Arthur C. Eastwood, Cleveland, Ohio. App. filed July 27, 1903. Details.

762,622. MAGNETIC CLUTCH; Arthur C. Eastwood, Cleveland, Ohio. App. filed March 5, 1904. A series of plates alternately carried by the two clutch members, provided with an arrangement of wedges to take up the wear, a coil supplying the necessary magnetism to bring the plates into frictional contact.

762,623. MAGNETIC CLUTCH; Arthur C. Eastwood, Cleveland, Ohio. App. filed April 1, 1904. The two magnetic members together form one clutch member and clamp between them the edge of the other clutch member, the latter not being in the magnetic field.

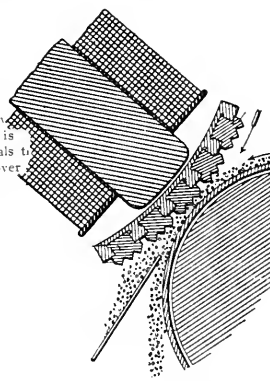
762,628. APPARATUS FOR PROMOTING FLOW OF OIL AND GAS IN WELLS; Fulton Gardner, Chicago, Ill. App. filed Jan. 25, 1904. A number of electric heaters arranged to be placed at intervals in a well and connected on one circuit.

762,644. ELECTRIC KEY SELECTING AND STRIKING MECHANISM; Andrew J. Leonard, Denver, Colo. App. filed Feb. 21, 1902. A number of comparatively small magnets are used to select the key to be operated, while a single large magnet accomplishes the striking of any selected key.

762,669. INSULATED RAIL JOINT; George A. Weber and Percy Holbrook, New York, N. Y. App. filed Nov. 13, 1903. An insulated rail joint, comprising the meeting ends of pairs of rails, with a plurality of longitudinally-extending filling blocks arranged side by side between the rails, and bolts for securing the parts of the joint together.

762,671. AUTOMATIC POTENTIAL REGULATOR; Wm. S. Andrews, Schenectady, N. Y. App. filed Oct. 1, 1902. The invention consists of a multiple pole switch having a plurality of pairs of stationary contact segments, a movable arm carrying a single pair of contacts adapted to bridge each pair of stationary segments in succession and terminals connected with the contacts on the arm and adapted to be connected with a voltmeter.

762,675. MULTIPLE POLE VOLTMETER SWITCH; Charles C. Badeau, Schenectady, N. Y. App. filed July 27, 1901. The connector is used between cars and the male and female parts are so constructed that it is impossible to connect together any except the terminals of the same circuit.



762,752.—Apparatus for Magnetic Separation.

762,684. CONNECTOR; Frank E. Case, Schenectady, N. Y. App. filed Oct. 3, 1902. Details.

762,686. ELECTRIC RAILROAD CROSSING SIGNAL; Thomas C. Clark, Cambridge, Ohio. App. filed Dec. 29, 1903. Details.

762,695. SIGNALING APPARATUS; Ernest A. Faller, New York, N. Y. App. filed Oct. 14, 1903. By this apparatus it is proposed to effect from one operation such as the pushing of a button, all that is necessary to provide the motive power for the sending of a signal as well as the locking of the mechanism against duplicate use.

762,697. REACTANCE COIL; John J. Frank, Schenectady, N. Y. App. filed Oct. 16, 1902. A fluid-cooled reactance coil, having a laminated core with air gaps formed in the layers to increase the magnetic reluctance and prevent the formation of stray fields.

762,709. ELECTRIC MOTOR; Gaylord C. Hall, New York, N. Y. App. filed March 7, 1901. In combination with a motor and resistance, means for varying the resistance, oppositely actuated by the difference of potential around the motor and around the resistance.

762,715. ELECTRICAL BATTERY; Julius E. Hasche, Chicago, Ill. App. filed Feb. 8, 1904. (See page 1198.)

762,720. PORTABLE ELECTRIC LIGHT; Conrad Hubert, New York, N. Y. App. filed Jan. 25, 1904. A small pocket case containing battery cells and a bullseye lamp with circuit closer.

762,735. MANUFACTURE OF INSULATED OR COVERED WIRES AND MACHINE THEREFOR; Charles Martin, Nottingham, England. App. filed May 18, 1903. A machine for successively placing upon a wire layers of yarn and of rubber and finally a knitted layer.

762,738. AUTOMATIC REGULATOR FOR MOTORS; Hans S. Meyer, Rugby, England. App. filed Sept. 4, 1902. An induction motor-regulating device which will vary the potential so as to cause it to decrease with an increase of speed of the motor and to increase with a decrease of speed and which is controllable by the speed of the motor.

762,744. MEANS FOR REGULATING DYNAMO ELECTRIC MACHINES; Charles R. McKay, Cincinnati, Ohio. App. filed Nov. 23, 1901. A dynamometer connected across two of the leads of a three-phase circuit, actuates the arm of a rheostat connected across the armature terminals of a dynamo.

762,740. TROLLEY; Rowley K. Ortt, Reading, Pa. App. filed Nov. 4, 1903. The wheel is swiveled on ball bearings to turn laterally to accommodate itself to kinks in the wire.

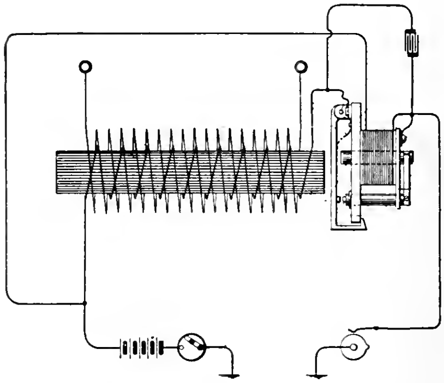
762,751. SEPARATING CYLINDER FOR MAGNETIC ...; Clarence Q. Payne, Stamford, Conn. App. filed Aug. 17, 190... vention consists in the shape of the pole faces whereby large con... face for the adherence of magnetic particles is provided.

762,752. APPARATUS FOR MAGNETIC SEPARATION; Clarence Payne, Stamford, Conn. App. filed Aug. 30, 1901. A modification of preceding invention.

762,753. APPARATUS FOR MAGNETIC SEPARATION; Clarence Payne, Stamford, Conn. App. filed Oct. 3, 1903. A further modification.

762,768. RAIL; Louis Steinberger, New York, N. Y. App. filed Dec. 16, 1903. The third rail is L-shaped in cross section and saddled loosely upon the supports which permit it to rock.

762,769. SUPPORT FOR RAILS; Louis Steinberger, New York, N. Y. App. filed Feb. 11, 1904. Another construction permitting of freedom of movement of an ordinary **T-third rail.**



762,776.—Induction Coil Vibrator.

762,770. DOOR OPENING APPARATUS; Henry S. Stewart, Chicago, Ill. App. filed March 24, 1904. A magnet controls a dog that holds a door from opening under the tension of a spring; by operating a push button, the door is released and opened.

762,776. INDUCTION COIL VIBRATOR; Richard Varley, Providence, R. I. App. filed Jan. 22, 1904. The vibrator is in a floating condition between the head of the coil on one side and a magnet on the other; the current automatically shunts from one coil to the other and thus actuates the vibrator in opposite directions. All adjusting screws are avoided and the vibrator can be hermetically sealed.

762,791. TROLLEY HANGER; Montraville M. Wood, Schenectady, N. Y. App. filed Dec. 15, 1902. Details.

762,792. ELECTRIC RAILWAY APPARATUS; Granville T. Woods, New York, N. Y. App. filed Oct. 12, 1901. The delivery of current to the sections of a sectional conductor is controlled by four magnets, whose circuits depend upon one another.

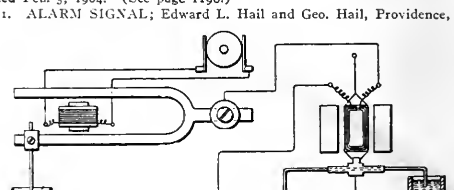
762,798. RAILWAY SIGNALING SYSTEM; Marion A. Born, Lawrenceville, Ga. App. filed Nov. 7, 1902. Details.

762,803. ELECTRICAL ACCUMULATOR; Alfred Jean Baptiste Maxime Colletas, Paris, France. App. filed Sept. 12, 1901. (See page 1198.)

762,812. ELECTRIC SIGNALING SYSTEM; John Dianovszky, Passaic, N. J. App. filed July 18, 1903. Details.

762,820. ELECTRIC TELEPHONE; Ernst Gundlach, Berwyn, Ill. App. filed Feb. 5, 1904. (See page 1198.)

762,821. ALARM SIGNAL; Edward L. Hail and Geo. Hail, Providence, R. I. App. filed May 14, 1902. An elevator car approaching a landing from either direction sounds a signal at the landing until the landing is passed.



762,829.—Receiver for Wireless Telegraphy.

762,823. TROLLEY WHEEL; Stewart J. Hanlin, Allegheny, Pa. App. filed March 29, 1904. Two trolley wheels mounted in tandem.

762,824. FUSE PLUG; Rudolph Hundhausen, Wilmersdorf, Germany. App. filed Nov. 24, 1899. Details.

762,829. RECEIVER FOR WIRELESS TELEGRAPHY; Oliver J. Lodge, Birmingham, Alexander Muirhead, Shortlands, and Edward E. Robinson, Birmingham, Eng. App. filed July 28, 1902. A wave detector consisting of two conducting surfaces having a film of fluid between them capable of being broken down upon the occurrence of a wave and immediately renewing itself.

762,831. TROLLEY BASE; Peter D. Milloy, Buffalo, N. Y. App. filed Oct. 27, 1902. Details.

762,840. FEED WIRE CONNECTION; Geo. L. Osborn, Boston, Mass. App. filed Sept. 2, 1902. A bracket intended to be soldered to the rail and having a pocket in which the end of the wire is soldered.

762,847. STORAGE BATTERY; Max Schneider, Dresden-Paulen, Germany. App. filed Sept. 4, 1903. (See page 1198.)
